The following terms and abbreviations are used in this report:

m<sup>2</sup> square meter  
mm millimeter  
μm micrometer

Temperature is given in degrees Celsius (°C) which can be converted to degrees Fahrenheit (°F) as follows:

$$^{\circ}\text{F} = 1.8 \times ^{\circ}\text{C} + 32$$

**Sea Level:** In this report, "sea level" refers to the National Geodetic Vertical Datum of 1929—a geodetic datum derived from a general adjustment of the first-order level nets of the United States and Canada, formerly called Sea Level Datum of 1929.

# Benthic-Invertebrate and Streambed-Sediment Data for the White River and Its Tributaries in and near Indianapolis, Indiana, 1994–96

By Danny E. Renn

## Abstract

Data were collected in the White River and its tributaries in and near Indianapolis, Indiana, on the diversity and density of benthic invertebrates; concentrations of metals, insecticides, herbicides, and semivolatile organic compounds sorbed on streambed sediments; and particle-size distribution of streambed sediments. A total of 369 benthic-invertebrate samples were collected at 21 sites during late spring or summer and early fall 1994 through 1996; of these, 30 were quality-control samples. A total of 33 streambed-sediment samples were collected at 14 sites during August 1994, 1995, and 1996; of these, 10 were quality-control samples.

## Introduction

Approximately 40 mi<sup>2</sup> of the city of Indianapolis is serviced by a combined-sewer system (fig. 1) (Howard Needles Tammen & Bergendoff, 1983). There are 137 combined-sewer outfalls in the Indianapolis area that discharge into the White River and its tributaries; 29 combined-sewer outfalls discharge directly into the White River, 28 to Fall Creek, 6 to Eagle Creek, 49 to Pleasant Run, 4 to Bean Creek, and 21 to Pogues Run (written commun., Indianapolis Department of Public Works).

The City of Indianapolis is responsible for managing its combined-sewer system and for determining strategies to mitigate the effect of combined-sewer overflows on receiving streams in and near Indianapolis (fig. 1). To evaluate

impacts of the sewer overflows and to develop the strategies, the City needs information on stream quality.

In 1993, the Indianapolis Department of Public Works (DPW) and the U.S. Geological Survey (USGS) began a cooperative study to determine the diversity and density of benthic invertebrates; concentrations of selected metals, insecticides, herbicides, and semivolatile organic compounds sorbed on streambed sediments; and particle-size distribution of streambed sediments in the White River and its tributaries in and near Indianapolis. The study was intended to supplement an existing river-quality-monitoring network operated by the department. While water samples reflect stream quality only at the time of sampling, benthic-invertebrate populations reflect long-term and short-term water-quality conditions because of their limited mobility. The differing sensitivity of benthic invertebrates to particular contaminants allows the presence or absence of particular types of benthic invertebrates to be used as an indicator of stream quality. Additionally, benthic invertebrates are found in all aquatic habitats and are easy to collect (Lenat and others, 1980). Chemical constituents sorbed on streambed sediments are not as transient as chemical constituents in the water column. Consequently, concentrations of these metals, insecticides, herbicides, and semivolatile organic compounds sorbed on streambed sediments also can be used as indicators of long-term water-quality conditions. Because of the positive correlation between decreasing particle size and increasing chemical concentrations in sediment (Horowitz, 1991), the particle-size distribution of streambed sediments can be used to help determine the variability in chemical constituents sorbed on streambed sediments.

## Purpose and Scope

This report provides information on sampling locations and data collected as part of this study for sites on the White River and its tributaries in and near Indianapolis. Data collected include (1) the diversity and density of benthic invertebrates; (2) the concentrations of metals, insecticides, herbicides, and semivolatile organic compounds sorbed on streambed sediments; and (3) the particle-size distribution of streambed sediments. From 1994 through 1996, 369 benthic invertebrate samples were collected at 21 sites, and 33 streambed sediments were collected at 14 sites.

## Description of Study Area

The study focuses on the White River and selected tributaries in and near the city of Indianapolis. The drainage area of the White River above the confluence of the East Fork White River is 5,372 mi<sup>2</sup>. The study area encompasses a 979-mi<sup>2</sup> drainage area that is 18.2 percent of the White River Basin above the confluence of the East Fork White River. The study used 21 sampling sites: 18 in Marion County, 1 in Hamilton County, and 2 in Morgan County. Indianapolis, the capital of Indiana, is the largest city in the State and is incorporated with Marion County. Marion County has a population of 783,042 (Bureau of the Census, 1990) and a surface area of 402 mi<sup>2</sup> (Sturm and Gilbert, 1978).

The study area is underlain by limestone; dolomite; siltstone; and shale of Silurian, Devonian, and Mississippian ages (Gray and others, 1987). The soils adjacent to the White River and its tributaries in the study area are loam soils that formed in unconsolidated glacial outwash that consists of stratified silt to boulder-size deposits and alluvium that consists of stratified sand to gravel-size deposits (Sturm and Gilbert, 1978). In most of the study area, these deposits range in thickness from 50 to 100 ft, but in the lower part of the study area these deposits can be less than 50 ft thick (Gray, 1983). The remaining soils in

the study area are silt-loam soils that formed in unconsolidated glacial till consisting of non-stratified silt to boulder-size deposits (Sturm and Gilbert, 1978). In most of the study area these glacial till deposits range in thickness from 100 to 250 ft, but in the lower part of the study area these deposits can be less than 50 ft thick (Gray, 1983). The study area is located in the Tipton Till Plain physiographic unit (Schneider, 1966), which is rolling to gently rolling in the area of glacial till deposits and generally flat in the areas covered by glacial outwash and alluvium.

The streams in the study area generally have low slopes and meandering channels that primarily contain silt to gravel-size material with areas of cobble to boulder-size material that generally form run and riffle areas. In the study area are four low-head dams on the White River and two low-head dams on Fall Creek (figure 1). These dams raise the level of the streams, decrease the streamflow velocities, and increase travel time through the pooled sections of the stream. Land use in the area of Indianapolis is primarily urban, and land use outside the Indianapolis area is primarily agricultural and forest.

The White River and its two largest tributaries, Fall Creek and Eagle Creek, are the major sources of water for public and industrial supply for Indianapolis because they generally have sufficient streamflows even during dry periods (Duwelius, 1990). Flows in Fall Creek are affected by Geist Reservoir, which has a storage capacity of 6.9 billion gallons at a reservoir elevation of 785 ft above sea level (Herring, 1974). Flows in Eagle Creek are affected by Eagle Creek Reservoir, which has a storage capacity of 7.8 billion gallons at a reservoir elevation of 790 ft above sea level (Herring, 1974). These reservoirs generally attenuate high streamflows and augment low streamflows.

The study area is located in the central climate division in Indiana and has a continental-type climate characterized by hot, humid summers and cold, wet winters (Newman, 1966). The mean precipitation in the central climate division for the

<sup>1</sup>Hoggatt, 1975.

period 1961 through 1990 was 40.5 in. (Stewart and others, 1995). During the study period, precipitation in the central climate division was 38.8 in. in 1994 (Stewart and others, 1995); 35.5 in., 1995 (Stewart and others, 1996); and 44.5 in., 1996 (Stewart and others, 1997).

## Methods of Data Collection

A total of 21 sampling sites were located on the White River and its tributaries (table 1). Ten sites were on the White River, one on Williams Creek, two on Fall Creek, two on Eagle Creek, two on Pleasant Run, two on Bean Creek, and two on Pogues Run. Benthic invertebrates were sampled at all 21 sites to determine diversity and density. Streambed-sediment samples were collected at 14 sites to determine concentrations of metals, insecticides, herbicides, and semivolatile organic compounds sorbed on the streambed sediments and to determine particle-size distributions of streambed sediments.

### Hydrologic Conditions

Samples were collected during periods of low-flow or steady-state streamflow conditions. After review of the USGS streamflow-gaging records in the study area, several sites were selected to be representative of streamflow conditions at all the sampling sites. Table 2 shows monthly mean streamflows during the sampling periods for the streamgage sites and monthly precipitation in the central climate division in Indiana. Table 2 data represent streamflow conditions at sites having drainage areas from 7.58 mi<sup>2</sup> to 1,898 mi<sup>2</sup>. Drainage areas at sampling sites on the White River range from 1,147 mi<sup>2</sup> to 2,126 mi<sup>2</sup> (table 1) and on the tributaries from 4.00 mi<sup>2</sup> to 317 mi<sup>2</sup> (table 1) (Hoggatt, 1975). Although monthly mean streamflow during the study period was frequently higher than the long-term mean for the period of record, samples were collected following a period of low-flow conditions and

during steady-state streamflow conditions. During the study period, monthly precipitation generally was greater than the long-term mean-monthly precipitation during the months of April, May, and June. During July, August, and September, precipitation was generally lower than the mean-monthly precipitation.

### Collection of Benthic Invertebrates

Throughout the study, samples were collected at 21 sites in the study area to determine the diversity and density of benthic invertebrates. Benthic invertebrates were collected at 19 of these sites during May and September 1994. After a review of the 1994 data and consultation with DPW, 1 site was discontinued and 2 sites were added; 20 sites were sampled during July and September 1995 and September 1996. (Data, however, are not available for the Williams Creek site for September 1995.) During July 1996, only 16 sites were sampled before a storm caused high water that prevented access to the remaining number of sites. At each site, three samples from different locations within the stream channel were collected during each sampling event. Three quality-control samples were collected at two sites during May and September 1994 and July and September 1995, and at one site during July 1996 and September 1996. A total of 369 benthic-invertebrate samples were collected during the study, including the 30 quality-control samples.

The three samples collected at each site were the minimum number needed to determine the diversity and density of benthic invertebrates at a site (Britton and Greeson, 1988). Benthic-invertebrate samples were collected twice a year during periods when most species are expected to be in early aquatic stages and prior to their adult terrestrial stage. At each site, samples were collected in habitat areas where the greatest diversity and density of benthic invertebrates were expected. The habitat areas were generally riffle

areas with gravel to cobble-size substrate material. Streams did not have identical morphology and sites varied in habitat conditions ranging from riffles to pooled areas, each with various sizes of substrate material. A description of the physical characteristics at each sampling site is contained in [table 3 \(at back of report\)](#).

A Surber sampler was used to collect benthic-invertebrate samples. The Surber sampler had a 0.0929-m<sup>2</sup> sample grid and a collection-net-bag mesh opening of 210 µm (U.S. Standard No. 70 sieve size); this mesh size has been recommended by the USGS for collecting benthic invertebrates (Britton and Greeson, 1988). To collect benthic-invertebrate samples, the bottom edge of the Surber sampler was pressed tightly against the bottom of the stream to isolate the sampling area. To remove the benthic invertebrates from the area enclosed by the sampler, the larger rocks were put in a bucket and the remaining streambed materials enclosed by the grid were scrubbed thoroughly so that the disturbed materials released from the streambed were collected in the Surber net. The rocks put in the bucket also were scrubbed, and the materials cleaned from the rocks were collected. The contents of the net and the bucket were combined and sieved through a mesh opening of 210 µm. The benthic invertebrates collected on the mesh screen were put in a container and fixed with a 10-percent Formalin solution. The benthic invertebrates were classified by a contract laboratory, TAI Environmental Sciences, Inc. Taxonomic nomenclature used in this report conform to the usage of Merritt and Cummins (1984) and Pennak (1989). The results of the taxonomic identification and counts are contained in [tables 4 through 126 at the back of this report](#).

## Collection of Streambed Sediments

Streambed sediments were collected at 14 sites to determine physical properties; concentrations of metals, insecticides, herbicides, and semivolatile organic compounds sorbed on streambed sediments ([table 127](#)); and particle-size

distributions of the streambed sediments. All samples were collected during August. Samples were collected at 12 sites during 1994. After a review of the data and consultation with DPW, eight sites were discontinued and two sites were added; six sites were sampled during 1995. After a review of the 1994 and 1995 data, five of the previously sampled sites were selected to be sampled during 1996. Ten quality-control samples were collected at six sites during 1994 and at two sites during 1995 and 1996. A total of 33 streambed-sediment samples were collected during the study.

No standard USGS method has been established for collection of streambed sediments in stream cross sections (Ward and Harr, 1990). For this study, each streambed-sediment sample consisted of two independently collected sub-samples. One sub-sample was collected for the analysis of metals and particle-size determinations and one sub-sample was collected for the analysis of insecticides, herbicides, and semi-volatile organic compounds. For both sub-samples, approximately equal volumes of the top 1 in. of fine-grained sediments were collected to represent the stream at that site. To avoid cross-contamination during sample collection, sub-samples were collected from downstream to upstream. The quality-control samples were collected upstream, or on opposite sides of the stream, from where the other samples were collected.

Polypropylene scoops and containers were used to collect and store the sediment analyzed for metals and particle-size distribution. The sediment was sieved through a polyethylene-sided 2-mm mesh screen. The sieved sediment was collected in a polyethylene pan and composited with a polypropylene scoop. Two representative samples of the composite were submitted for analysis, one for the analysis of metals and one for determination of particle-size distribution. Samples for the analysis of metals were chilled to 4°C and sent to the USGS National Water Quality Laboratory in Arvada, Colo., for analysis. Particle-size distributions were determined by the USGS sediment laboratory in Iowa City, Iowa.

**Table 127.** Physical properties measured during sampling; metals, insecticides, herbicides, and semivolatile organic compounds analyzed from streambed-sediment samples from the White River and its tributaries in and near Indianapolis, Indiana  
[Brackets [ ] and ALL CAPS indicate name as it appears in table 128]

| Phenol [PHENOL(C6H-5OH)]                                    | Pyrene                     |

---

All equipment used for collection of the metals sub-sample was cleaned and decontaminated before each sample was collected. After each sample collection, all equipment was scrubbed thoroughly and rinsed with native-stream water, tap water, and deionized water. All equipment then was rinsed thoroughly with a 5-percent nitric-acid solution followed by a rinse with deionized water. Before samples were collected, all equipment was rinsed three times with native-stream water. For the first sample collection, except for the use of native-stream water, all equipment was cleaned and decontaminated with the same procedures at the USGS Indiana District laboratory.

Glass beakers were used to collect and store the sediment analyzed for insecticides, herbicides, and semivolatile organic compounds. The sediment was sieved through a 2-mm stainless-steel mesh screen. The sieved sediment was collected in a glass pan and composited with a glass beaker. Three representative samples of the composite were submitted for analysis: one for insecticides, one for herbicides, and one for semivolatile organic compounds. All samples were chilled to 4°C and sent to the USGS National Water Quality Laboratory for analysis.

All equipment used for collection of the insecticides, herbicides, and semivolatile organic compounds sub-sample was cleaned and decontaminated before samples were collected. After each sample collection, all equipment was scrubbed thoroughly and rinsed with native-stream water, tap water, and deionized water. All equipment then was rinsed thoroughly with methanol.

Before samples were collected, all equipment was rinsed three times with native-stream water. For the first sample collection, except for the use of native-stream water, all equipment was cleaned and decontaminated with the same procedures at the USGS Indiana District laboratory. Table 128 (at back of report) lists data for physical properties; concentrations of metals, insecticides, herbicides, and semivolatile organic compounds; and particle-size distribution of streambed sediments determined at each site.

## Summary

Data were collected in the White River and its tributaries in and near Indianapolis, Ind., during a cooperative study between the Indianapolis DPW and the USGS from 1994 through 1996. These data were collected to provide information on the diversity and density of benthic invertebrates; concentrations of metals, insecticides, herbicides, and semivolatile organic compounds sorbed on streambed sediments; and particle-size distributions of streambed sediments. This information may be used to help determine control strategies for mitigating the effects of combined-sewer overflows on receiving streams.

A total of 369 benthic-invertebrate samples were collected at 21 sites during late spring or summer and early fall 1994 through 1996; of these, 30 were quality-control samples. A total of 33 streambed-sediment samples were collected at 14 sites during August 1994, 1995, and 1996; of these, 10 were quality-control samples.

| <b>Ancillary information:</b>                                  | Site is located in the center of Indianapolis. Sampling location under the bridge had faster streamflow velocities and greater amount of gravel and cobble than other sampling sites. Sampling location under the bridge generally not in sunlight. Fines were generally black organic material, and some of the gravel and cobble-size material was manmade material (broken concrete, bricks)                         |
| <b>Field identifier:</b>                                       | WRHARD-3  |
| <b>Site name:</b>  | White River at Harding Street, Indianapolis, IN   |
| <b>USGS site-identification number:</b>                        | 03353193  |
| <b>Drainage area, mi<sup>2</sup>:</b>                          | <sup>1</sup> 1,660  |
| <b>Sampling location:</b>                                      | Spring 1994—two sites on the left side of the stream, 200 feet downstream from Harding Street bridge and one site on right side of stream, 25 feet downstream from large combined-sewer outfalls; fall 1994—on right side of stream, 25 feet downstream from large combined-sewer outfalls; all other samplings—on right side of stream downstream from the bridge and upstream from large combined-sewer outfalls      |
| <b>Stream-channel type:</b>                                    | Natural, with levees close to stream  |
| <b>Bank vegetation:</b>  | Trees upstream and grass/weeds downstream from Harding Street bridge  |
| <b>Land use in general vicinity of stream:</b>                 | Urban   |
| <b>Flow characteristics:</b>                                   | Pool  |
| <b>Substrate size in stream reach (estimated)<sup>2</sup>:</b> | Fines, cobble, and gravel   |
| <b>Substrate size sampled (estimated)<sup>2</sup>:</b>         | Cobble and gravel, with some fines  |
| <b>Ancillary information:</b>                                  | There are large combined-sewer outfalls 75 feet downstream from the bridge. The site is located 1.15 miles upstream from the outfall for the Belmont advanced wastewater-treatment plant and 1.75 miles upstream from the dam at the Stout Generating Station, which creates the pooled condition. The fines were generally black organic material, and the cobble and gravel-size material was primarily crushed stone |

| <b>Substrate size in stream reach (estimated)<sup>2</sup>:</b> | Fines, sand, gravel, cobble, boulder  |
| <b>Substrate size sampled (estimated)<sup>2</sup>:</b>         | Cobble and gravel   |
| <b>Ancillary information:</b>                                  | At Vermont Street, Pogues Run goes under Indianapolis and outfalls into the White River. Fines were generally black organic material and the gravel, cobble, and boulder-size material was generally manmade material (broken concrete, bricks) |

---

<sup>1</sup>From Hoggatt (1975).

<sup>2</sup>Listed in order of predominance.

<sup>3</sup>Estimated value from Hoggatt (1975).

## Abbreviations Used in Tables 4 through 126

|                         |   |
|-------------------------|---|
| $\mu\text{S}/\text{cm}$ | Specific conductance of water is expressed in micro-siemens per centimeter at 25 degrees Celsius ( $\mu\text{S}/\text{cm}$ ). This unit is equivalent to micromhos per centimeter at 25 degrees Celsius ( $\mu\text{mho}/\text{cm}$ ), formerly used by the U.S. Geological Survey. |
| $^{\circ}\text{C}$      | degrees Celsius   |
| $\text{mi}^2$           | square miles  |
| $\text{m}^2$            | square meter  |
| $\text{mg}/\text{L}$    | Chemical concentration is given in milligrams per liter.  |

**NOTE:** Blanks in tables indicate no organisms found.

**Table 4.** Benthic-invertebrate data for station 400001086012301 White River at 146th Street near Noblesville, IN

[sp., species]

Field identifier: WR146-0

Habitat: gravel and cobble; run

Specific conductance: 665  $\mu\text{S}/\text{cm}$  at 25°C

Date: May 16, 1994

Drainage area: 1,147  $\text{mi}^2$ 

Dissolved oxygen: 11.4 mg/L

Time: 1420

Water temperature: 18.5°C

pH: 8.35 units

**Table 6.** Benthic-invertebrate data for station 03353000 White River at Indianapolis, IN (Morris Street)

[sp., species]

Field identifier: WRINDY-2                      Habitat: gravel and cobble, with some fines and sand; run                      Specific conductance: 666  $\mu\text{S}/\text{cm}$  at 25°C  
 Date: May 18, 1994                      Drainage area: 1,635  $\text{mi}^2$                       Dissolved oxygen: 11.1  $\text{mg}/\text{L}$   
 Time: 1330                      Water temperature: 19.2°C                      pH: 8.33 units

**Table 13.** Benthic-invertebrate data for station 03351072 Williams Creek at 96th Street, Indianapolis, IN

[sp., species]

Field identifier: WC96-12                      Habitat: cobble and gravel; riffle                      Specific conductance: 647  $\mu\text{S}/\text{cm}$  at 25°C  
 Date: May 16, 1994                      Drainage area: 17.0  $\text{mi}^2$                       Dissolved oxygen: 9.4  $\text{mg}/\text{L}$   
 Time: 1040                      Water temperature: 16.4°C                      pH: 7.89 units

**Table 79.** Benthic-invertebrate data for station 395259086001601 Fall Creek at 71st Street near Lawrence, IN  
[sp., species]

Field identifier: FC71-16

Habitat: cobble and gravel; run

Specific conductance: 450 µs/cm at 25°C

Date: September 12, 1995

Drainage area: 243 mi<sup>2</sup>

Dissolved oxygen: 6.8 mg/L

Time: 1300

Water temperature: 22.4°C

pH: 7.77 units

**Table 89.** Benthic-invertebrate data for station 400001086012301 White River at 146th Street near Noblesville, IN

[sp., species]

Field identifier: WR146-0

Date: July 17, 1996

Time: 1030

Habitat: gravel and cobble; run

Drainage area: 1,147 mi<sup>2</sup>

Water temperature: 26.6°C

Specific conductance: 783 µs/cm at 25°C

Dissolved oxygen: 9.6 mg/L

pH: 8.29 units

**Table 102.** Benthic-invertebrate data for station 394349086080001 Bean Creek at Southern Avenue at Indianapolis, IN

[sp., species]

Field identifier: BCSOU-15                      Habitat: gravel and cobble; riffle                      Specific conductance: 424  $\mu\text{S}/\text{cm}$  at 25°C  
 Date: July 15, 1996                      Drainage area: 5.00  $\text{mi}^2$                       Dissolved oxygen: 7.7 mg/L  
 Time: 0900                      Water temperature: 20.9°C                      pH: 7.79 units

**Table 104.** Benthic-invertebrate data for station 394746086055601 Pogues Run at East 21st Street at Indianapolis, IN

[sp., species]

Field identifier: POR21-14

Date: July 16, 1996

Time: 1430

Habitat: cobble and gravel; riffle

Drainage area: 4.40 mi<sup>2</sup>

Water temperature: 23.6°C

Specific conductance: 637 µs/cm at 25°C

Dissolved oxygen: 8.4 mg/L

pH: 7.92 units

**Table 109.** Benthic-invertebrate data for station 03353193 White River at Harding Street, Indianapolis, IN  
[sp., species]

Field identifier: WRHARD-3

Habitat: cobble and gravel, with some fines; pool

Specific conductance: 914 μs/cm at 25°C

Date: September 11, 1996

Drainage area: 1,660 mi<sup>2</sup>

Dissolved oxygen: 7.5 mg/L

Time: 1115

Water temperature: 24.2°C

pH: 7.74 units

**Table 118.** Benthic-invertebrate data for station 03352875 Fall Creek at 16th Street at Indianapolis, IN  
[sp., species]

Field identifier: FC16-10

Habitat: cobble and gravel; riffle

Specific conductance: 763 µs/cm at 25°C

Date: September 12, 1996

Drainage area: 317 mi<sup>2</sup>

Dissolved oxygen: 7.1 mg/L

Time: 0845

Water temperature: 22.0°C

pH: 7.63 units
