Historical Late-Winter and Spring Snowpack Depth and Equivalent Water-Content Data for Maine

By Glenn A. Hodgkins and Robert W. Dudley, U.S. Geological Survey
Marc C. Loiselle, Maine Geological Survey

Abstract

Late-winter and spring snowpack depth and equivalent water-content data are presented for 37 snow-survey sites in and near Maine. Data from the sites span at least 50 years up to the present (2004), and are at least 50-percent complete for the first and for the second half of their record. The oldest measurements at the 37 snow-survey sites in this report are from 1906.

Introduction

The equivalent water content (also known as water equivalent) of snowpack is the amount of water contained in snow, in a frozen state, on the ground surface. Water from the melting snowpack runs off into streams, rivers, and lakes and recharges the ground-water system, typically in late winter and spring. Flood-forecasting agencies, people who live near rivers and streams, and many water-dependent industries need to know how much snowmelt water to expect each year.

The Maine Cooperative Snow Survey Program, run jointly by the Maine Department of Conservation, Maine Geological Survey (MGS) and the U.S. Geological Survey (USGS), compiles snowpack data collected on a regular basis (currently weekly, historically biweekly) in late-winter and spring. Data are collected by various private companies and government agencies including electric-power utilities, water-power companies, pulp and paper companies, the National Weather Service (NWS), the MGS, and the USGS, in cooperation with the State of Maine. Snowpack depth and equivalent water content have been measured at selected snow-survey sites in Maine for more than 90 years. Statewide equivalent water-content maps are currently available shortly after each snow survey in late winter and early spring on the Internet at <http://www.state.me.us/mema/weather/snow.htm>.

Hayes (1972) published a summary map report of snowpack data in Maine based on a compilation of data for the period 1941 through 1965. This report was the first statewide publication on mean equivalent water content of the snowpack. In addition to mean equivalent water content, the Hayes report shows the average density of the snowpack on March 1 and the aver-

age date of maximum water content of the snowpack across the State. Loiselle and others (1992) did a preliminary analysis of maximum equivalent water content across Maine and trends over time at two snow-survey sites. Loiselle and Hodgkins (2002) used snowpack equivalent water-content data from 109 snow-survey sites with an average of 43 years of record to generate a map of maximum observed equivalent water content and a map of mean equivalent water content in the snowpack on or about March 1. Dudley and Hodgkins (2002) analyzed trends over time in snowpack depth, equivalent water content, and density for sites in coastal Maine.

This report presents snowpack depth and equivalent water-content data for snow-survey sites that have at least 50 years of relatively complete data up to the present (2004). This criteria is explained more in the next section. The data presented in this report can be used by State and local governments, water-resources agencies, power companies, engineering design professionals, biologists, and others who are interested in late-winter and spring snowpack in Maine during the past century.

Snowpack Depth and Equivalent Water-Content Data for Maine

The sources of snow-survey data used in this report include the USGS; the MGS; the NWS; the New Hampshire Department of Environmental Services; PDI New England, Inc. (formerly part of Maine Public Service Company); PPL Maine, LLC (formerly part of Bangor Hydro-Electric Company); Kennebec Water Power Co.; FPL Energy of Maine, LLC (formerly part of Union Water Power Company); Domtar Inc. (formerly Georgia Pacific Corp.); Great Lakes Hydro America, LLC (formerly Great Northern Paper, Inc.); and Sappi Limited (formerly S.D. Warren Company).

Snowpack depth and equivalent water content have been measured at selected snow-survey sites in Maine for more than 90 years. This is done by twisting a hollow snow tube through the full thickness of the snowpack. Both "Mt. Rose" (also known as "Federal") style tubes (1.5-in. diameter aluminum tubes with steel cutting teeth) and "Adirondack" style tubes (2.5-in. diameter fiberglass tubes with steel cutting teeth) have

2 Historical Late-Winter and Spring Snowpack Depth and Equivalent Water-Content Data for Maine

been used. The snowpack depth for both types of tubes is measured with a scale on the outside of the tube, and the water content is measured by weighing the tube (with and without the snow). These measurements are repeated at multiple locations, typically 10 at each site, for each date that snowpack is measured, and then averaged. Most of the snow-survey sites are located in flat or gently sloping areas of mixed hardwood and conifer forest. Measurements are not taken near conifers.

In 1991, the USGS and the MGS began to compile all historical snow-survey data for the state. The compilation was completed in 1993 and has been supplemented with additional measurements annually since then. Locations of snow-survey sites were digitized into a geographic information system and linked to a tabular database containing the date of measurement, snowpack depth, and equivalent water content. Several quality-assurance checks of the data were performed. Site identification numbers, dates, and measurements were examined to eliminate duplicate entries in the tabular database. Snowpack depths, equivalent water contents, and calculated densities (equivalent water content divided by depth) were screened for unreasonable values, and anomalous entries were checked. As of summer 2004, the database contained approximately 24,400 measurements made at 319 snow-survey sites. Currently each year, about 70 sites are measured weekly in the late winter/early spring and about 200 sites are measured on or near March 1.

For this report, data were again screened for unreasonable values. During snowmelt, snowpack densities usually range from 0.30 to 0.55 (Gray and Prowse, 1993). Values exceeding 0.60 are suspicious, if not erroneous. Snowpack in eastern North America sometimes includes a basal ice layer that can affect the average density of a snowpack, particularly that of a shallow snowpack (Dr. R.E. Davis, Technical Director, U.S. Army Corps. of Engineers, Engineer Research and Development Center, Cold Regions Research and Engineering Laboratory, oral commun., 2002). All snowpack measurements with densities greater than 0.60 or zero density were examined. Data in this report are considered questionable if the density was zero, or if it exceeded 0.60 and the snowpack depth was greater than 6 in., unless other measurements at the site (prior to or after the measurement in question) corroborate the measurement. Seven snowpack measurements from six sites in this report are considered questionable. These measurements are noted in the appropriate data tables in the back of the report.

The data in this report were compiled as part of a larger effort to analyze changes over time in late-winter/spring snowpack in Maine for sites with long-term record. Snowpack depth and equivalent water-content data were analyzed for those sites with record spanning at least 50 years of data, up to the present (2004). To be analyzed in this study, the sites were required to have at least 50-percent complete data for the first and second half of their record, for at least one sampling window. Sampling windows are defined as 15-day windows centered on February 15, March 1, March 15, April 1, April 15, and May 1. The exact date of the sampling at a snow-survey site varies from year to

year. Sites often do not have data for every year for a given sampling window. As an example of the 50-percent complete criteria, if a site had data from 1941 through 2004 for a given sampling window then that site must have had at least 16 years of data in the sampling window, for the period 1941 through 1972 and also for the period 1973 through 2004.

Thirty-seven snow-survey sites in and near Maine met the described criteria (table 1, fig. 1). All the historical snowpack depth and equivalent water-content data for these sites are presented in tables 2 through 38. The site with the longest recorded snow-survey data is site 1028 (Aziscohos/Aziscohos Dam (UWP)), which has its first measurements in 1906. The site with the shortest record is site 1289 (Dallas (KWP)), which has its first measurements in 1953. The initials in the site names are part of the historical name. Most of them refer to the company who originated the site: KWP, Kennebec Water Power; BH, Bangor Hydro-Electric; UWP, Union Water Power; GNP, Great Northern Paper. The initial "B" is a unique site identifier that likely indicates that the site has moved over time. There is very little historical site information available for the snow-survey sites in this report. Some sites have been moved away from the local effects of development, extensive logging, or unacceptable amounts of conifer growth.

Prior to the 1990's, zero values of snowpack depth and equivalent water content may not have been recorded and archived, particularly in April in southern and coastal areas of the State. This could result in a bias if the data are tested for trends over time.
