INTRODUCTORY NOTE

The Hawaiian Volcano Observatory Summaries have been published in the current format since 1956. The Quarterly Summaries (1956 through 1973) and the Annual Summaries (1974 through 1985) were originally published as Administrative Reports. These reports have been compiled and published as U.S. Geological Survey Open-File Reports. The quarterly reports have been combined and published as one annual summary. All the summaries from 1956 to the present are now available as .pdf files at http://www.usgs.gov/pubprod.

The earthquake summary data are presented as a listing of origin time, depth, magnitude, and other location parameters. Network instrumentation, field station sites, and location algorithms are described. Tilt and other deformation data are included until Summary 77, January to December 1977. From 1978, the seismic and deformation data are published separately, due to differing schedules of data reduction.

There are eight quarters—from the fourth quarter of 1959 to the third quarter of 1961—that were never published. Two of these (4th quarter 1959, 1st quarter 1960) have now been published, using handwritten notes of Jerry Eaton (HVO seismologist at the time) and his colleagues. The seismic records for the remaining six summaries went back to California in 1961 with Jerry Eaton. Other responsibilities intervened, and the seismic summaries were never prepared.

Chronology

The following Kīlauea eruption chronology covers the two recent reports and the six missing quarters:

Location	Beginning Date	Ending Date	Comment
Kīlauea Iki crater (Kīlauea's summit)	11/14/1959	12/20/1959	19 eruptive episodes
Kapoho (lower east rift zone)	1/13/1960	2/18/1960	4 eruption stages
Halemaumau (Kīlauea's summit)	2/24/1961	2/24/1961	Intermittent activity during uninterrupted inflation following the 1960 eruption
Halemaumau (Kīlauea's summit)	3/22/1961	3/25/1961	Same as above.
Halemaumau (Kīlauea's summit)	7/10/1961	7/17/1961	Same as above.
Heiheiahulu (middle east rift zone)	9/22/1961	9/25/1961	First historical east rift eruption at this location

The 1959-1960 eruptions were among two of the most spectacular Kīlauea eruptions. The HVO staff was kept busy with acquisition of unusually high quantities of instrumental data and observations of the two sequences, which were separated by less than one month. Even with a year's interval before the beginning of the summit-east rift sequence in 1961, the staff never caught up, and the seismic records were set aside for later study.

A total of 1,672 earthquakes—1,106 for 1960 and 566 for 1961—are part of HVO's cataloged database. The annual listings have been appended to the 1st Quarter Report of 1960 and to the 4th Quarter Report for 1961. The number of earthquakes is probably low, biased toward the larger magnitudes. The entire HVO catalog, including 1960 and 1961, is accessible from the ANSS CATALOG SEARCH site at http://www.ncedc.org/anss/catalog-search.

Chronological Summary

The first quarter of 1964 showed less activity associated with the volcanoes than has been experienced for several years. Mauna Loa continues to appear calm, and Kilauea has shown no restlessness, although the density of sulfurous fumes and the amount of sulfur stain on the lava crusts have increased.

January 7, about 01^h00^m--some residents of the Hilo and Puna Districts were awakened by a quake of magnitude 3.7 and about 8 km deep along the Poliokeawe fault system, southeast of Makaopuhi, near the coast; 44 small aftershocks were recorded.

January 29-February 6--a cluster of seismic events included: a felt quake on the east flank of Mauna Loa, a felt quake 30 km deep of magnitude 3.3 with 15 aftershocks, 2 half-hour spells of deep tremor, and more than 100 small shallow local Kilauea quakes in 5 consecutive days.

February 20 at 22^h32^m--residents of Maui and northern parts of Hawaii felt a quake of magnitude 4.3. The epicenter was located at about 13 km depth off the southwest shore of Maui.

March was ushered in by 3 days of more than a hundred shallow local Kilauea caldera quakes each, and ended with Alaska's Good Friday earthquake, its tsunami and aftershocks.

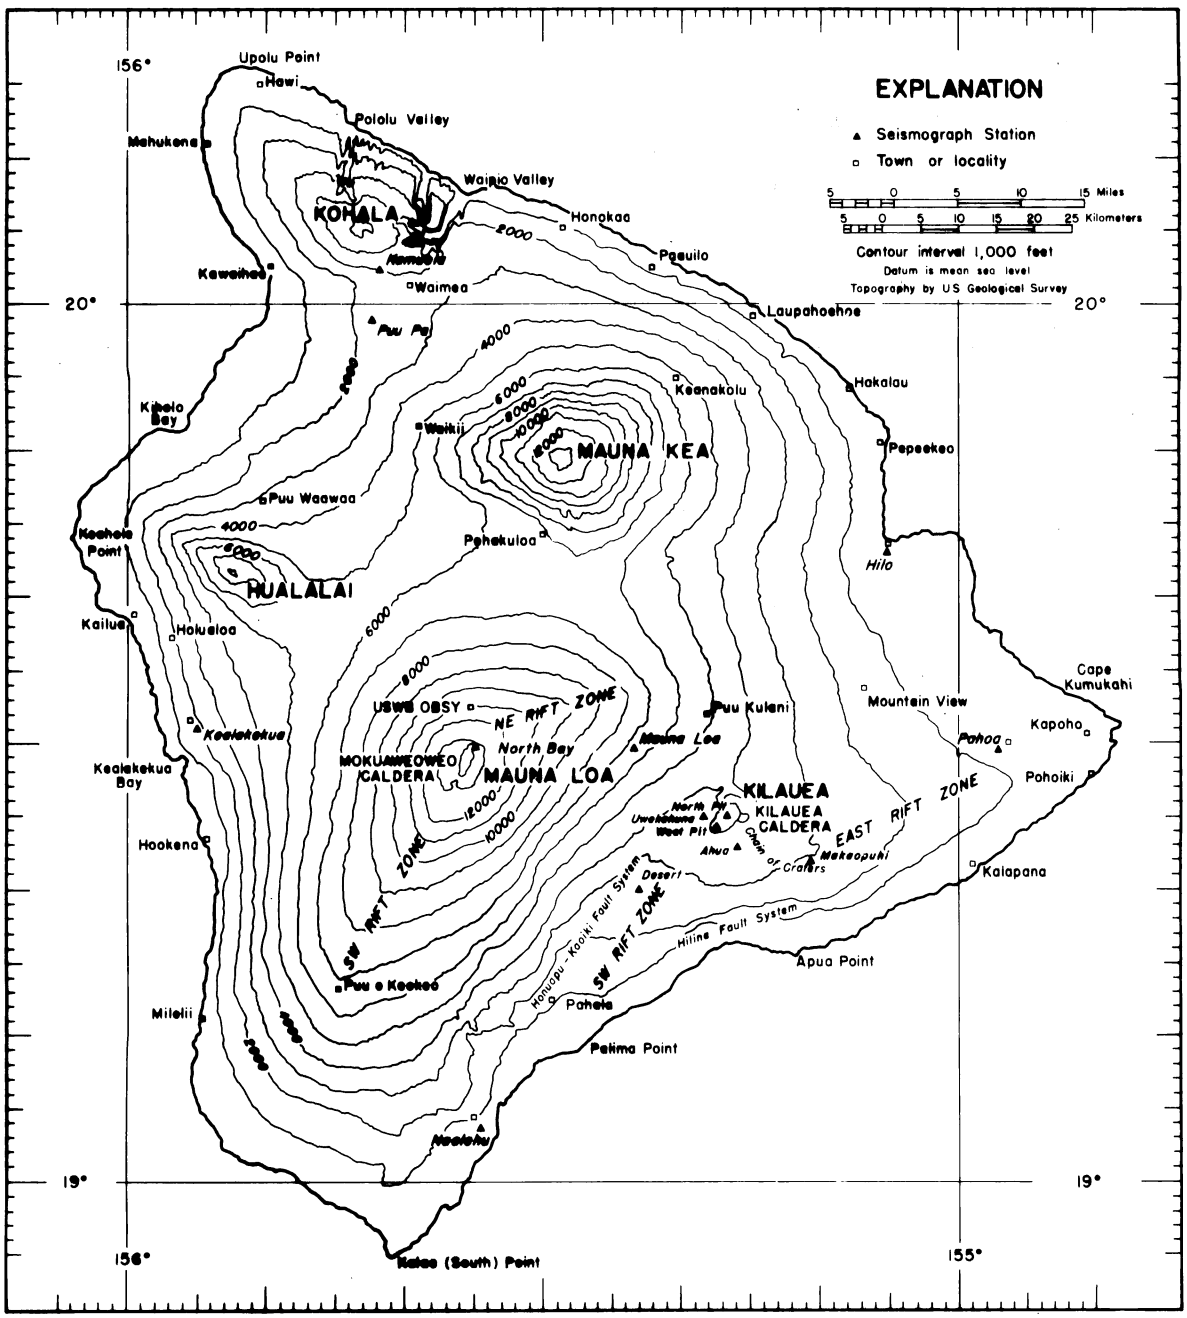

Figure 1.--Map of the island of Hawaii showing seismograph stations operated by the Geological Survey and localities mentioned in the text. Epicenters of local earthquakes are given in terms of geographic coordinates, which are indicated at the edges of the map.

Tilting of the ground around Kilauea caldera.--Tilting of the ground around the summit of Kilauea is monitored daily by a short-base water-tube tiltmeter in Uwekahuna Vault (table 1), and at irregular intervals it is measured on a regional scale by means of a network of field tilt bases and a portable water-tube tiltmeter. The attitude of the ground surface at each tilt base is reported in terms of north-south and east-west tilt coordinates. Both coordinates at each station were set equal to 500 when measurements at that station were begun. Increasing tilt coordinates correspond to northward and eastward tilting of the earth's surface, i.e., to a relative subsidence toward the north and east. A one-unit change in coordinate corresponds to a tilting of 1 microradian (1 mm per km) in the direction indicated.

Table 1.--Tilt coordinates at Uwekahuna Vault, January, February, and March 1964

Hilina Pali (19°18.2' N., 155°18.6' W.)	Not occupied this epoch					14
Kapapala Ranch (19°20.5' N., 155°23.8' W.)	21	495.2	503.3	0.6	S. 82° E.	11

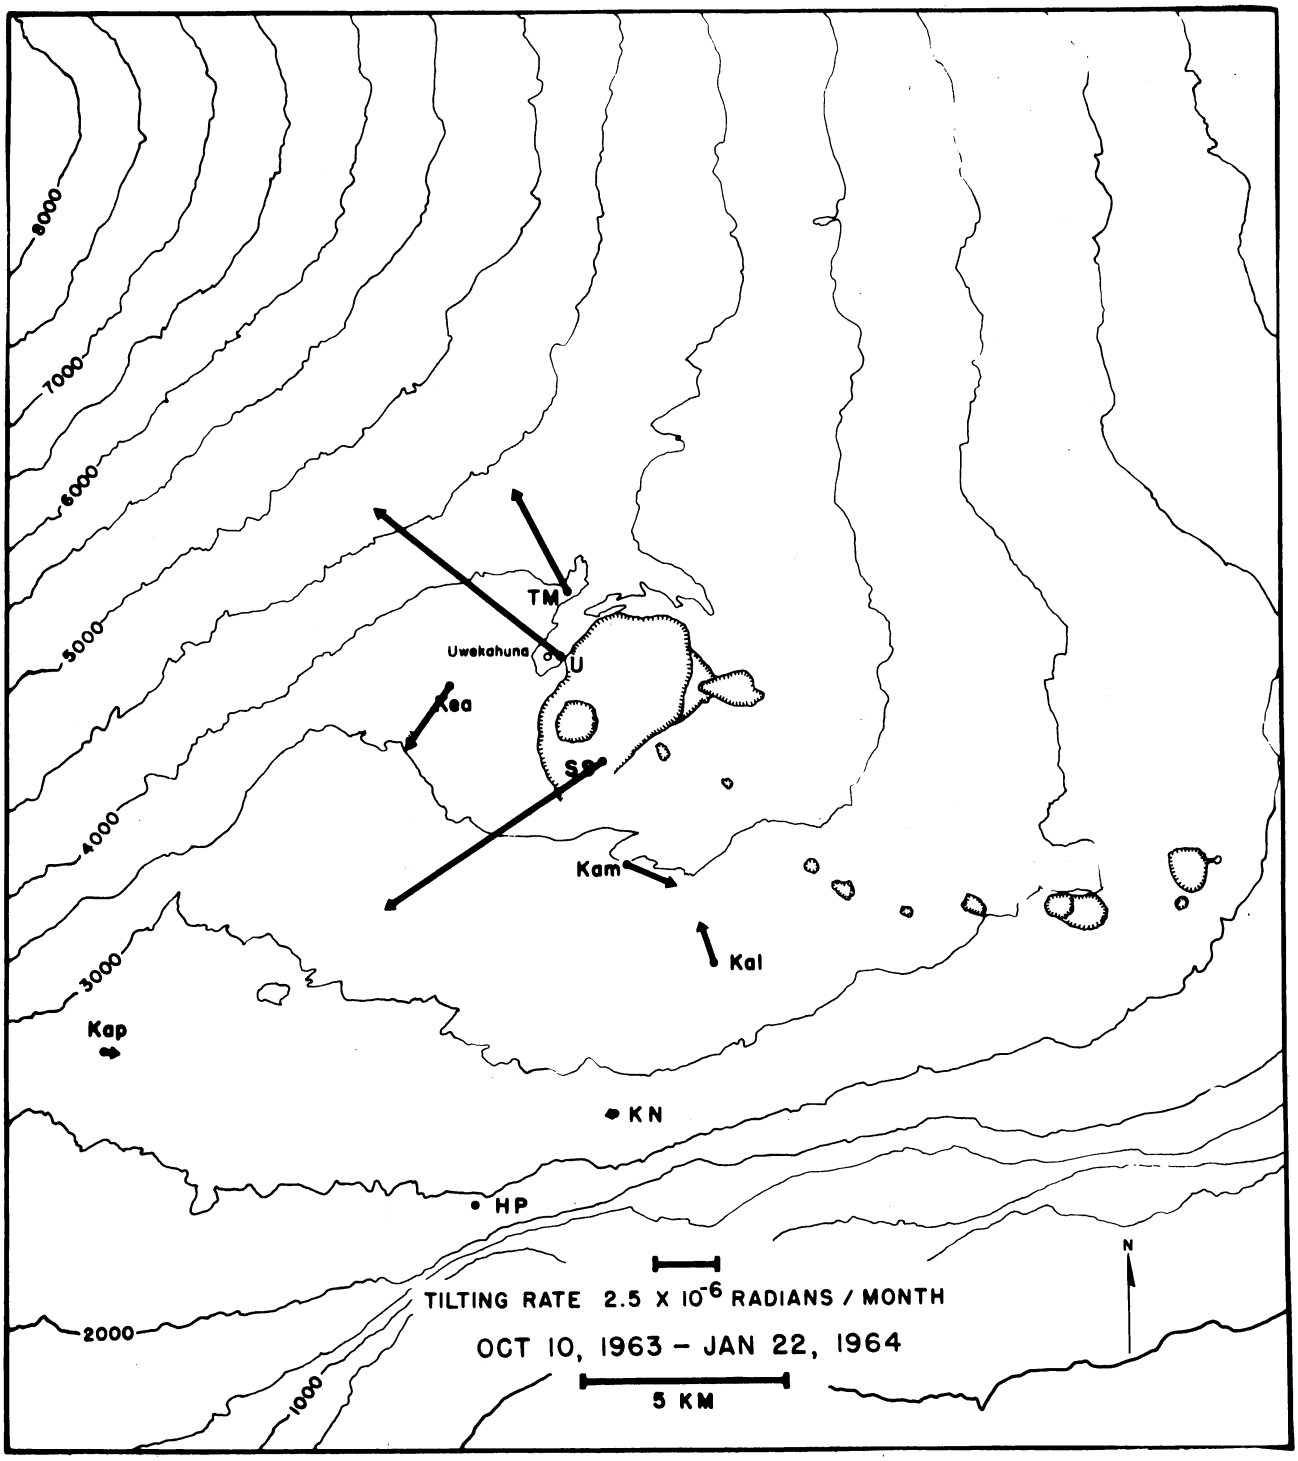

Figure 2.--Tilting of the ground around Kilauea caldera, Oct. 10, 1963 to Jan. 22, 1964. The vector depicting tilting at a given tilt base points in the direction of maximum relative subsidence and has a length proportional to the rate of tilting during the measurement interval. Closed circles represent field tilt bases; open circles, short-base water-tube tiltmeters.

Seismic summary.--Events recorded by the U.S. Geological Survey seismograph network in Hawaii fall into two categories: local earthquakes and tremor originating in the region of the Hawaiian Islands, usually within 100 km of at least one seismograph, and distant earthquakes originating more than 3,000 km from Hawaii. As an index of seismic activity at Hawaiian volcanoes, daily counts of earthquakes and minutes of tremor recorded by seismographs in Hawaii are listed in table 3. The earthquakes are separated into groups on the basis of region of origin as determined by analysis of records obtained daily at the Observatory (U, M, A, D, N, WP, MP). Earthquakes of magnitude 2.5 or greater are generally sufficiently well recorded to be located with greater precision; they are listed individually in table 4. Data on identifiable phases from distant earthquakes are listed in table 5.

Locations of the seismograph stations are shown on figure 1, and essential data on the stations are listed in table 6.

Table 3.--Number of earthquakes and minutes of tremor recorded on seismographs U, M, A, D, N, WP, and MP around Kilauea caldera

Tremor is separated into three categories: deep, intermediate, and shallow, on the basis of relative amplitudes on seismographs in the summit region. Unless otherwise stated, tremor is presumed to be associated with movement of magma within the central complex of Kilauea.

Earthquake categories are: Halemaumau rock slides, which are detected by the characteristic record they produce on the North Pit seismograph; shallow earthquakes in the Kilauea caldera region; shallow earthquakes along the SW. rift zone of Kilauea and the adjacent portion of the Kaoiki fault system; earthquakes along the eastern half of Kilauea's east rift zone--detected largely on the Pahoa short-period vertical; earthquakes from a source about 30 km beneath Halemaumau; earthquakes from the upper east rift zone and the adjacent fault systems of Kilauea's south flank (these are usually first arrivals at the Ahua meter or at the new experimental geophone near Makaopuhi Crater (MP)); and earthquakes from other regions: Kona, Mauna Kea, etc.

Date (1964)	Tremor (in minutes)			Earthquakes

Table 4.--Local earthquakes recorded by seismographs of the U.S. Geological Survey, January, February, and March 1964

[Entries for a given quake are: date, origin time (Hawaiian Standard Time), magnitude, depth, epicenter, and felt report. All earthquakes of magnitude 2.5 and larger, as well as many favorably located smaller ones, occurring on or near the island of Hawaii are included in the list.

In the following list some origin times are followed by "KM 30" and a statement of magnitude. These are all members of a continuing family of quakes noted also in other Summaries. The best mean focus for this group is beneath Halemaumau at a depth of 30 km (19°24.1' N., 155°17.1' W.).

In the following list a number of quakes are described as "Upper east rift" (see Summary 28). Their average epicenter is approximately 19°21.5' N., 155°14' W. about 2 km south of Aloi Crater at near-surface depth.

The mean focus of the magnitude 6.1 Kaoiki fault system earthquake of June 27, 1962, and its aftershocks is 19°24' N., 155°25' W., at a depth of 3-8 km. This focus has been abbreviated "Kaoiki"].

Table 5.--Distant earthquakes

[Times are reported in Greenwich Civil Time which is 10 hours faster than Hawaiian Standard Time. A "c" following the time of P indicates compressional first motion; a "d" indicates dilatational first motion. Station symbols, locations, and instrumentation are presented in table 6. Magnitudes calculated from the Hawaii seismograms are followed by (HVO). Location of epicenter, origin time, focal depth, and magnitude are taken from "Preliminary Determination of Epicenters" published by the U.S. Coast and Geodetic Survey.

The great number of aftershocks following the March 28 Alaskan earthquake necessitated a separate listing of these events (end of this table). Many Alaskan aftershocks continued to occur after the end of the quarter, and these will again be listed separately as "Alaskan aftershocks" in HVO Summary 34]

Table 6.--U.S. Geological Survey seismograph stations in Hawaii--Continued

---

1/ HVO-1 is a moving-coil, hinged, vertical-component seismograph with seismometer and galvanometer periods of 0.5 second. Over-damping of both seismometer and galvanometer is used to control the strong galvanometer reaction. This seismograph has a peak magnification of about 20,000 at a period of 0.25 second. Recording is optical, on photographic paper.

2/ HVO-2 is a moving-coil, vertical-component seismograph with a seismometer period of 0.8 second. Its signal is transmitted over telephone wires to the Hawaiian Volcano Observatory, where it is recorded on smoked paper. The response of this seismograph is similar to that of HVO-1. Records from these seismographs at M, A, and D, and at N, WP, and MP (Benioff) are recorded on two 3-component drums to permit more accurate comparison of arrival times at these stations.

The following persons or agencies reported "felt" earthquakes during the first quarter, 1964. Their assistance is gratefully acknowledged.

Chronological summary

Hawaiian volcanoes were exceptionally quiet during the second quarter of 1964. From April 1 to May 15 no measurable tilting was indicated by the short-base tiltmeter that is read daily. During this span of time there were a few bursts of tremor (April 16 to April 22) and six scattered earthquakes barely large enough to be felt. On May 23, in the Kaoiki fault system, an earthquake of magnitude 3 was followed by 27 aftershocks in less than 2 hours. A Kohala-centered quake of 3.5 magnitude was felt on May 28. Two quakes were felt on June 4, the first at about 08^h30^m from 45 km depth under Kilauea, and the second at about 13^h30^m, from a shallow quake on the southeast flank of Mauna Loa. Other quakes were felt on June 8, 17, and 18.

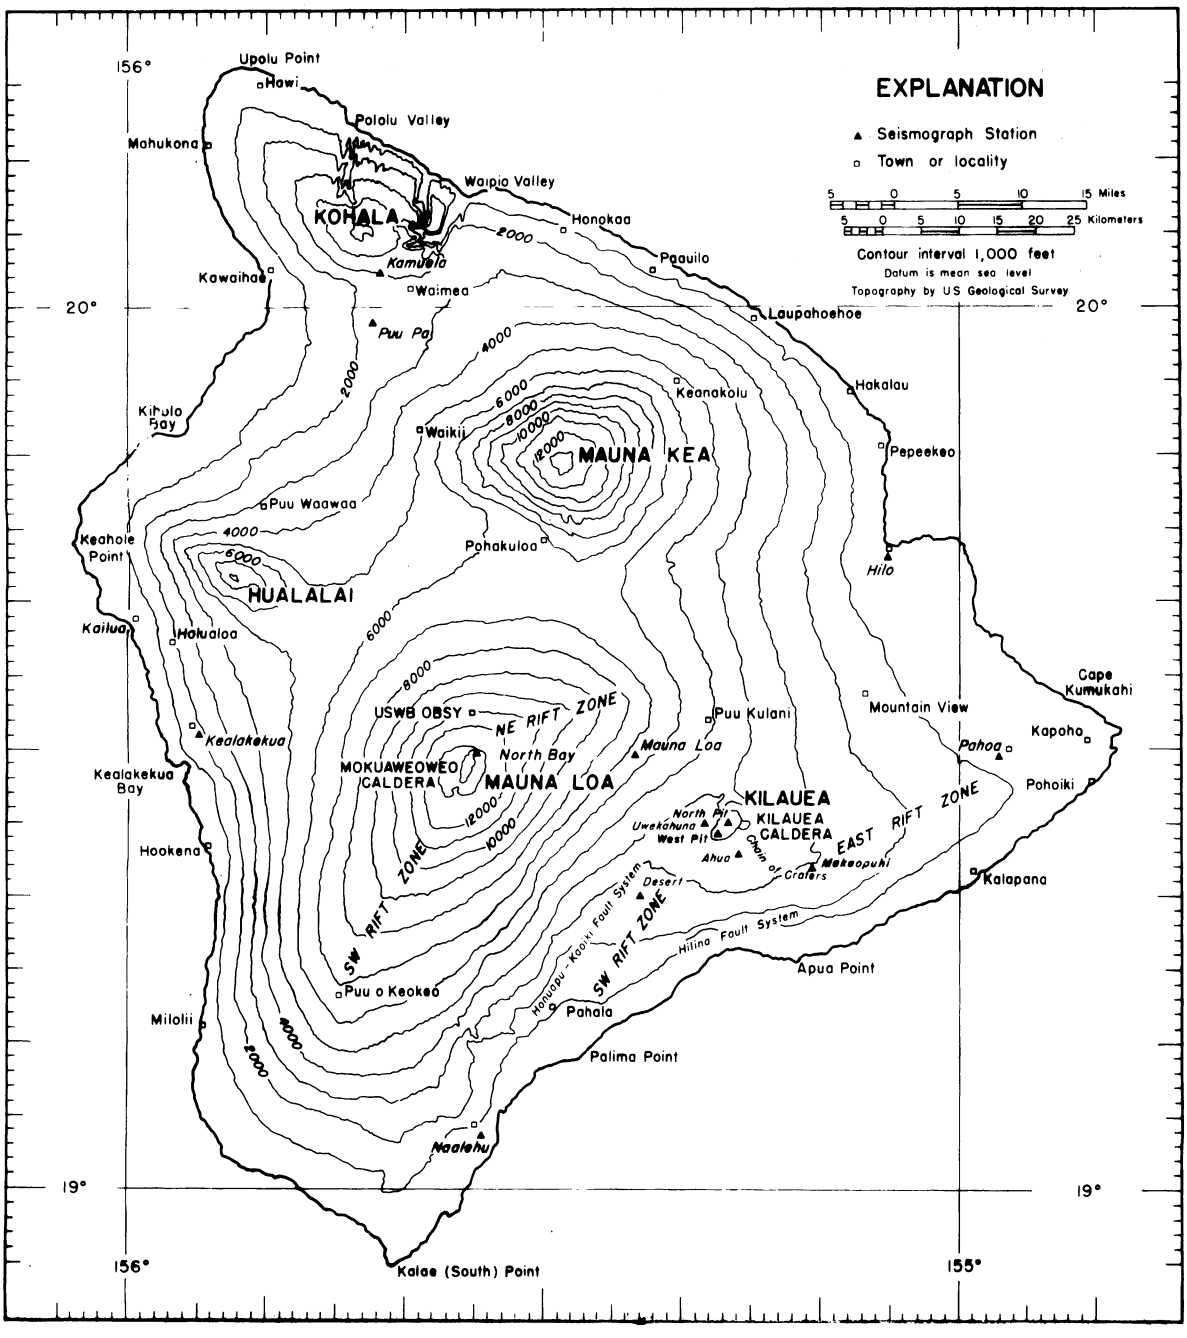

Figure 1.--Map of the island of Hawaii showing seismograph stations operated by the Geological Survey and localities mentioned in the text. Epicenters of local earthquakes are given in terms of geographic coordinates, which are indicated at the edges of the map.

Tilting of the ground around Kilauea caldera.--Tilting of the ground around the summit of Kilauea is monitored daily by a short-base water-tube tiltmeter in Uwekahuna Vault, and at irregular intervals it is measured on a regional scale by means of a network of field tilt-bases and a portable water-tube tiltmeter. The attitude of the ground surface at each tilt base is reported in terms of north-south and east-west tilt coordinates. Both coordinates at each station were arbitrarily set equal to 500 when measurements at that station were begun. Increasing tilt coordinates correspond to northward and eastward tilting of the earth's surface, i.e., to a relative subsidence toward the north and east. A one-unit change in coordinate corresponds to a tilting of 1 microradian (1 mm per km) in the direction indicated.

Kapapala Ranch (19°20.5' N., 155°23.8' W.)	April 28	495.3	502.3	0.3	N. 83.5° W.	Jan. 21, 1964

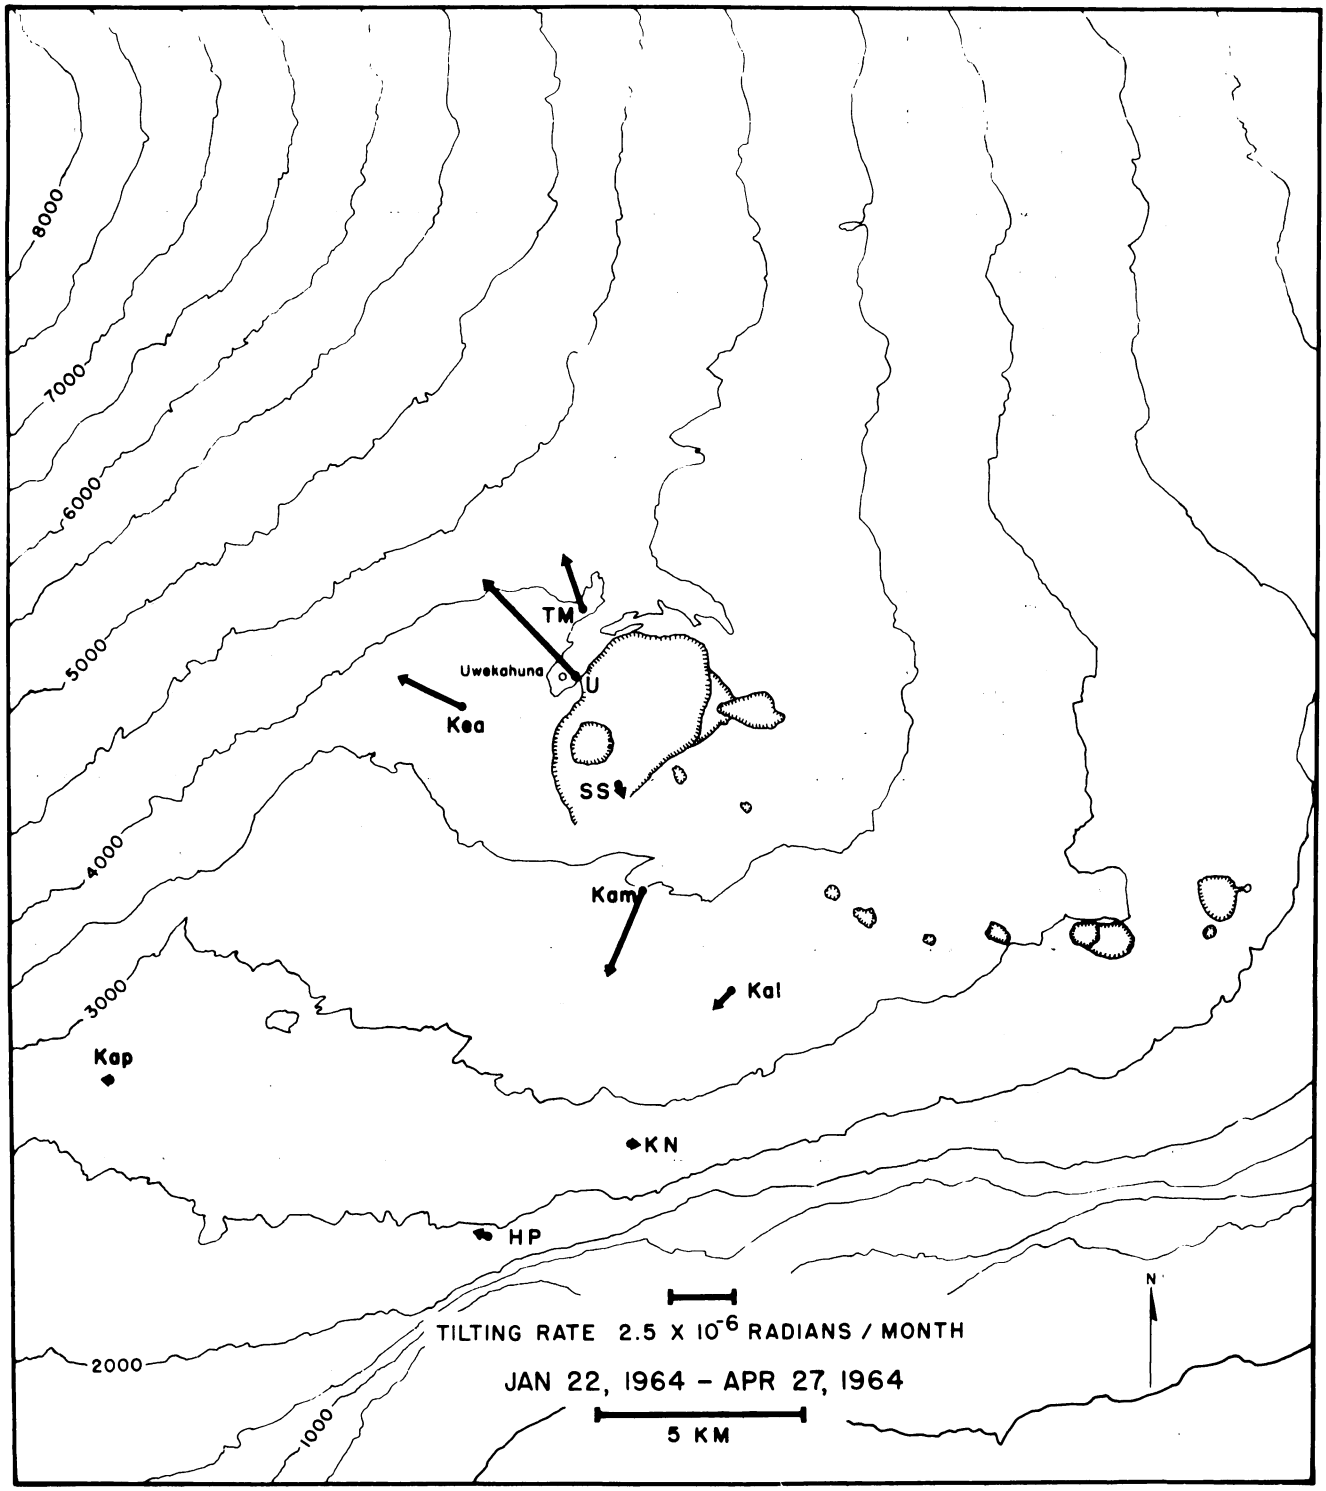

Figure 2.--Tilting of the ground around Kilauea caldera, January 22 to April 27, 1964. The vector depicting tilting at a given tilt base points in the direction of maximum relative subsidence and has a length proportional to the rate of tilting during the measurement interval. Closed circles represent field tilt bases; open circles, short-base water-tube tiltmeters.

Seismic summary.--Events recorded by the U.S. Geological Survey seismograph network in Hawaii fall into two categories: local earthquakes and tremor originating in the region of the Hawaiian Islands, usually within 100 km of at least one seismograph, and distant earthquakes originating more than 3,000 km from Hawaii. As an index of seismic activity at Hawaiian volcanoes, daily counts of earthquakes and minutes of tremor recorded by seismographs in Hawaii are listed in table 3. The earthquakes are separated into groups on the basis of region of origin as determined by analysis of records obtained daily at the Observatory (U, M, A, D, N, WV, MP). Earthquakes of magnitude 2.5 or greater are generally sufficiently well recorded to be located with greater precision; they are listed individually in table 4. Data on identifiable phases from distant earthquakes are listed in table 5.

Locations of the seismograph stations and essential data on the stations are listed in table 6, of summary 33.

Table 3.--Numbers of earthquakes and minutes of tremor recorded on seismographs U, M, A, D, N, WP, and MP around Kilauea caldera

Tremor is separated into three categories: deep, intermediate, and shallow, on the basis of relative amplitudes on seismographs in the summit region. Unless otherwise stated, tremor is presumed to be associated with movement of magma within the central complex of Kilauea.

Earthquake categories are: Halemaumau rock slides, which are detected by the characteristic record they produce on the North Pit seismopgraph; shallow earthquakes in the Kilauea caldera region; shallow earthquakes along the SW. rift zone of Kilauea and the adjacent portion of the Kaoiki fault system; earthquakes along the eastern half of Kilauea's east rift zone--detected largely on the Pahoa short-period vertical; earthquakes from a source about 30 km beneath Halemaumau; earthquakes from the upper east rift zone and the adjacent fault systems of Kilauea's south flank (these are usually first arrivals at the Ahua meter or at the new experimental seismometer near Makaopuhi Crater (MP)); and earthquakes from other regions: Kona, Mauna Kea, etc.

Date (1964)	Tremor (in minutes)			Earthquakes

Table 4.--Local earthquakes recorded by seismographs of the U.S. Geological Survey, April, May, and June 1964

[Entries for a given quake are: date, origin time (Hawaiian Standard Time), magnitude, depth, epicenter, and felt report. All earthquakes of magnitude 2.5 and larger, as well as many favorably located smaller ones, occurring on or near the island of Hawaii are included in the list.

In the following list, some origin times are followed only by "KM 30" and a statement of magnitude. These are all members of a continuing family of quakes noted also in other Summaries. The best mean focus for this group is beneath Halemaumau at a depth of 30 km (19°24.1' N., 155°17.1' W.).

In the following list a number of quakes are described as "Upper east rift" (see Summary 28). Their average epicenter is approximately 19°21.5' N., 155°14' W. about 2 km south of Aloi Crater at near-surface depth.

The mean focus of the magnitude 6.1 Kaoiki fault system earthquake of June 27, 1962, and its aftershocks is 19°24' N., 155°25' W., at a depth of 3-8 km. This focus has bee abbreviated "Kaoiki"]

Table 5.--Distant earthquakes

[Times are reported in Greenwich Civil Time which is 10 hours faster than Hawaiian Standard Time. A "c" following the time of P indicates compressional first motion; a "d" indicates dilatational first motion. Station symbols, locations, and instrumentation are presented in summary 33. Magnitudes calculated from the Hawaii seismograms are followed by (HVO). Location of epicenter, origin times, and focal depth, and magnitude reported by other institutions are taken from "Preliminary Determination of Epicenters" published by the U.S. Coast and Geodetic Survey.

The high concentration of aftershock activity following the March 28, 1964, Alaskan earthquake necessitated a separate listing of these events; and such is listed in the end of this table, as continued from summary 33]

Chronological summary

Most conspicuous during the third quarter of 1964 were the increase in sulfurous fuming from Halemaumau and the step-up in rate of inflation of Kilauea summit which was indicated by both the short-base tiltmeter and the net of long-base tiltmeters. The number of felt earthquakes increased (43 during the quarter), but the total daily counts of quakes remained very low.

During July the short-base tiltmeter indicated slight but erratic inflation of Kilauea. A flurry of small earthquakes from the Kaciki fault on July 16 lasted 3 hours. Two relatively large quakes were felt during July: one magnitude 4.5 earthquake from a shallow focus beneath the southeast flank of Kilauea was felt throughout eastern Hawaii on the 1st, and another magnitude 4.5 quake, offshore, west of Mauna Loa, was felt islandwide on the 17th.

In the first half of August the summit tilting accelerated to a rate sufficient to increase the elevation of Uwekahuna a tenth of an inch per day. The number of shallow quakes originating in the Kilauea caldera area increased to more than 100 per day, and tremor was conspicuous by its absence. On August 26 one deep magnitude 4.5 quake under Kilauea and another of the same magnitude off the northwest coast of Hawaii were felt islandwide. The daily count of local caldera quakes decreased on August 16 and remained low for the remainder of the quarter.

There was increased seismic activity near Pahoa on the lower east rift of Kilauea during the first half of September. An average of 25 small shallow earthquakes per day was recorded by the Pahoa seismograph. Several larger quakes with magnitudes of from 3.5 to 4 were felt strongly in the Puna region; a dozen smaller ones were felt only near Pahoa. This local activity was monitored on several occasions by a portable seismograph.

Inflation of the summit area continued at a lower rate during September, and no evidence suggesting movement of magma into the lower east rift zone was recorded.

An earthquake of magnitude 4.9 was felt throughout the island just after midnight on the morning of September 18. It originated at about 5-km depth on the southeast flank of Kilauea and was followed by about 50 smaller quakes, 2 of which were felt locally, during the next 24 hours.

Seismic profiles.--During August, Observatory personnel participated with the Branch of Crustal Studies in recording seismic-refraction profiles along the northeast, southeast, and west coasts of the triangular-shaped island of Hawaii. Shots were fired at 10-km intervals from the U.S. Coast Guard Cutter Cape Small, Lt. Lloyd commanding, and were recorded along each coast by five refraction units spaced approximately at 25-km intervals.

Interpretation of the seismograms by D. P. Hill indicates that the crust is about 16 km thick under the west flanks of Mauna Loa and Hualalai, and 11 km thick under the northeast and southeast flanks of Kilauea. The crust has an intermediate thickness along the northeast

flanks of Mauna Kea and the Kohala Mountains. The velocity of P waves in the upper crust increases with depth from 2.0 to as much as 6.0 km per sec.; velocities in the upper crust are generally lower on the flanks of Kilauea than on the flanks of the other volcanoes. Clearly recorded arrivals indicate that a layer with velocities of from 6.9 to 7.3 km per sec. forms the lowermost 4-8 km of the crust under each of the coasts. The velocity of P_n under each of the coasts is about 8.2 km per sec. Anomalously high crustal velocities are associated with the major rift zones extending from the five volcanoes that form the island.

Crustal Studies participants in the Hawaii refraction program were Wayne Jackson, David Stuart, Benton Tibbetts, and Jack Clark.

Puna leveling.--A 50-mile-long network of bench marks established in 1958 across part of the active east rift zone of Kilauea volcano in the Puna area was releveled during the second half of 1964. The level lines, which follow the road network, form one large triangle which encompasses a smaller triangle, thus affording three loop closures. These were at 0.075, 0.060, and 0.015 foot, and the survey was well within 3d-order allowable error. The rift zone is crossed in three places and paralleled roughly for several miles by the level lines. Spur lines were run to the Kupapau tide gage and to the Kokoolau triangulation station along the Honolulu Landing road.

Uplift of 0.3 foot has taken place across the rift zone along the Pahoa-Kaimu line. The zone of uplift is 7 miles wide, its apex asymmetric to the north. A small graben half a mile wide and 0.3 foot deep indents the apex. The swelling is probably related to the east rift eruption of September 1961, during which much more magma moved from beneath the summit region into the rift zone than was erupted along the rift.

The Pahoa-Pohoiki crossing of the rift shows a broad region of subsidence having a maximum depression of 0.2 foot. The line paralleling the rift zone near Kapoho shows a collapse of 0.2-0.4 foot, and the road along the shore between Kapoho and Pohoiki appears to have subsided about 0.1 foot. This general area of collapse along the rift zone east of Pahoa probably was formed during the 1960 Kapoho eruption.

Three stations north of the Kapoho graben along the Honolulu Landing road show a sharp uplift of 0.5 foot, which decreases rapidly to less than 0.1 foot within a distance of $1\frac{1}{2}$ miles. This uplift suggests that some vertical movement took place on the north side of the Koae fault immediately preceding and during the Kapoho eruption in 1960. The disturbed zone in the Honolulu Landing-Pohoiki region of the rift zone is about 6 miles wide.

New bench marks set in areas covered by the 1960 flows can be compared roughly with nearby but buried 1958 bench marks. This comparison provides a thickness profile for the 1960 flows which fill the Kapoho graben beneath the present Pohoiki-Honolulu Landing road. The maximum thickness exceeds 70 feet 0.7 mile north of the Kapoho road intersection without allowing for subsidence of the graben during the eruption.

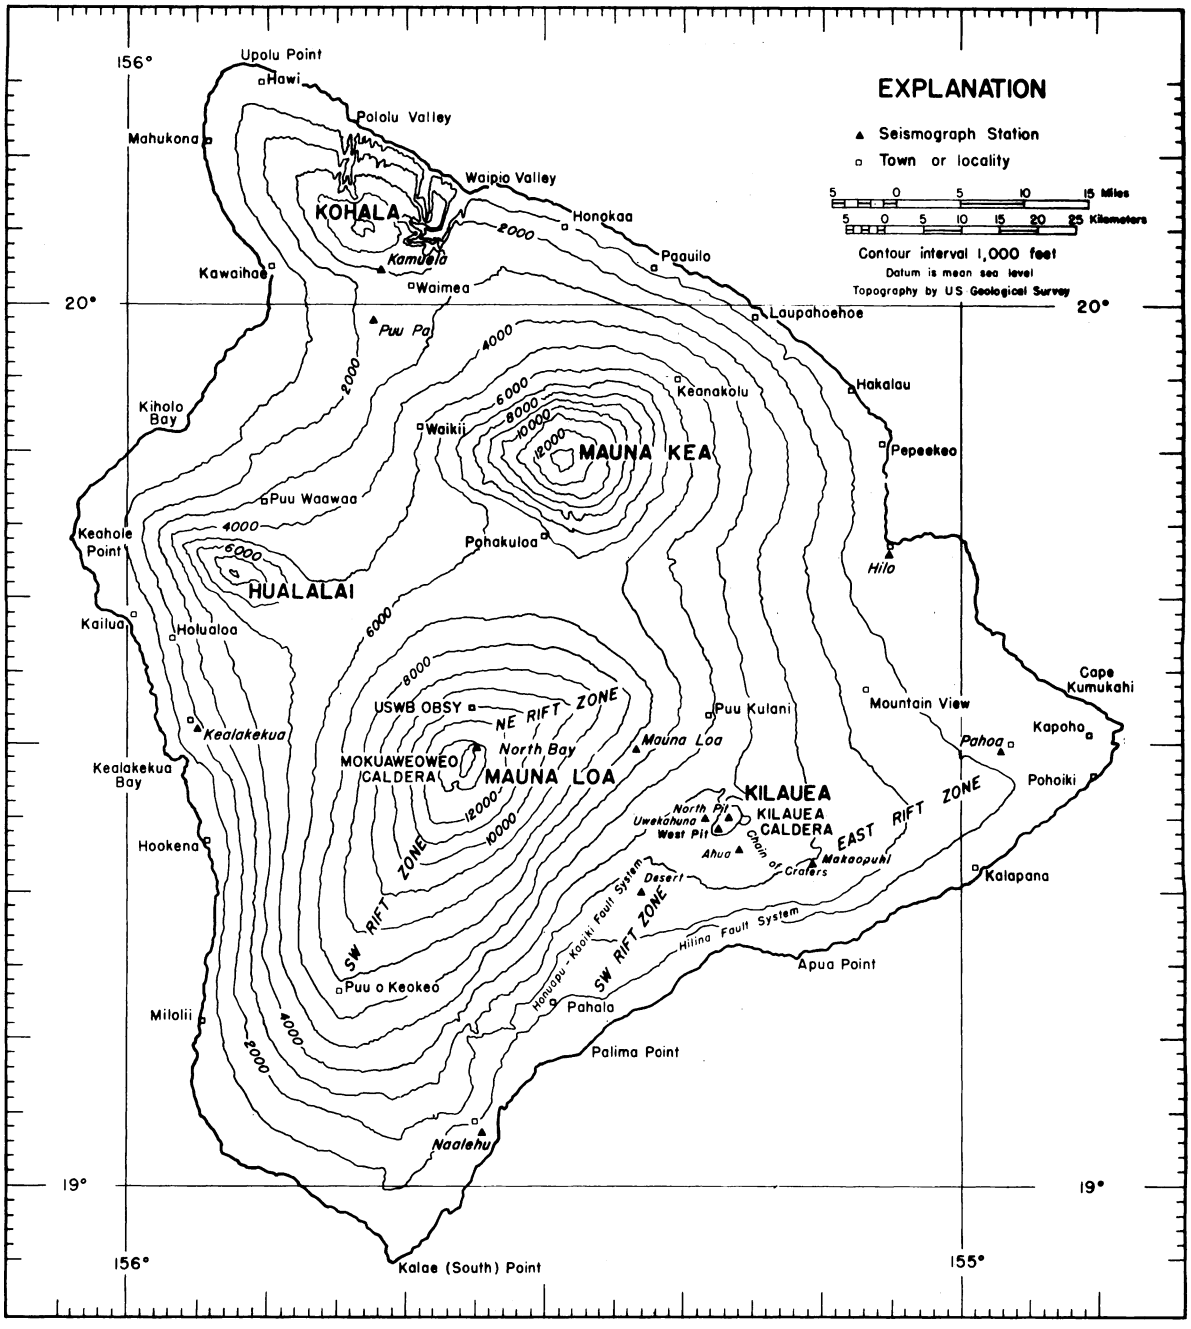

Figure 1.--Map of the island of Hawaii showing localities mentioned in the text and seismograph stations operated by the U.S. Geological Survey. Epicenters of local earthquakes are given in terms of geographic coordinates, which are indicated at the edges of the map.

Organization of the leveling fieldwork and analysis of the results were done by R. W. Decker, who was on sabbatical leave from Dartmouth College.

Tilting of the ground around Kilauea caldera.--Tilting of the ground around the summit of Kilauea is monitored daily by a short-base water-tube tiltmeter in Uwekahuna Vault, and at irregular intervals it is measured on a regional scale by means of a network of field tilt-bases and a portable water-tube tiltmeter. The attitude of the ground surface at each tilt-base is reported in terms of north-south and east-west tilt coordinates. Both coordinates at each station were arbitrarily set equal to 500 when measurements were begun. Increasing tilt coordinates correspond to northward and eastward tilting of the earth's surface; that is, to a relative subsidence toward the north and east. A one-unit change in coordinate corresponds to a tilting of 1 microradian (1 mm per km) in the direction indicated.

Ahua Kamokukolau	26	584.3	528.5	9.5	S. 6.0° W.	May 1
Kipuka Nene	Sept. 1	482.6	508.3	0.8	S. 32.3° W.	Apr. 27
Hilina Pali	Not occupied this epoch					
Kapapala Ranch	Aug. 24	493.9	504.0	0.4	S. 25.1° E.	Apr. 28

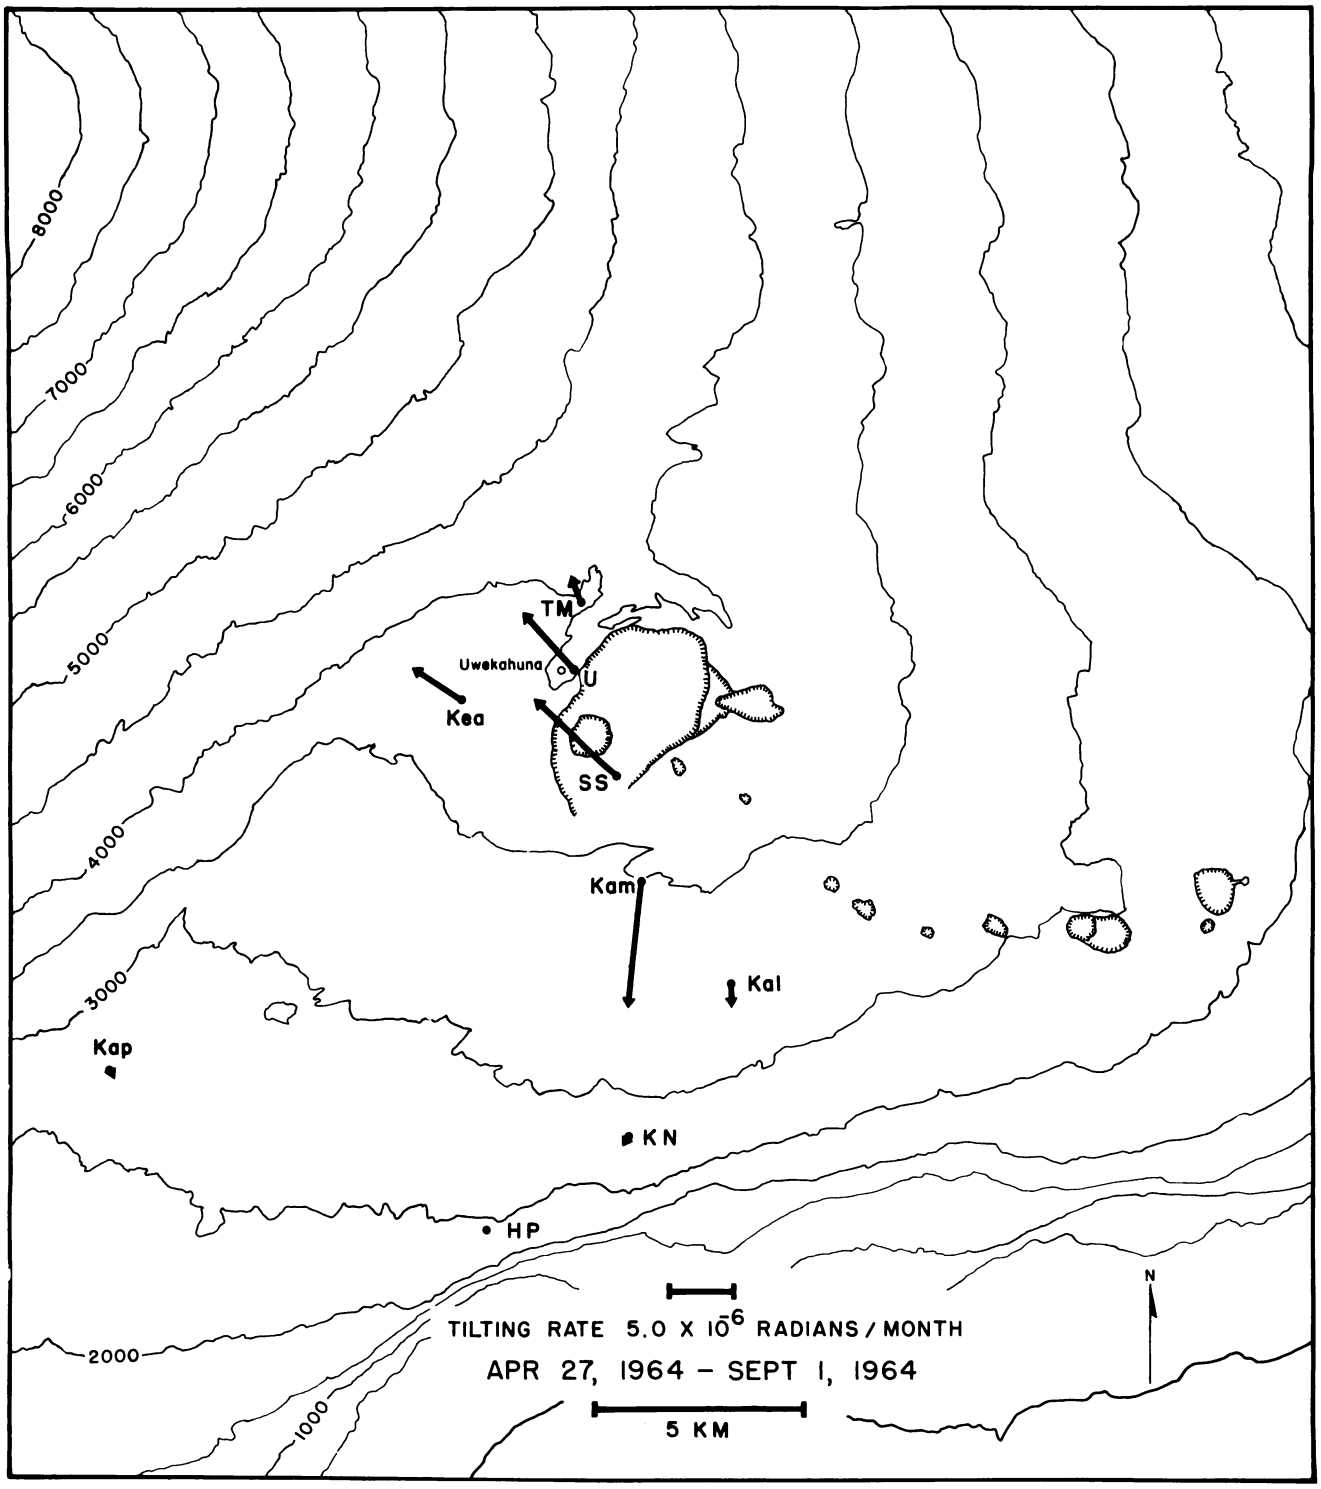

Figure 2.--Tilting of the ground around Kilauea caldera, April 27 to September 1, 1964. The vector depicting tilting at a given tilt base points in the direction of maximum relative subsidence and has a length proportional to the rate of tilting during the measurement interval. Closed circles represent field tilt bases; open circles, short-base water-tube tiltmeters.

Seismic summary.--Events recorded by the U.S. Geological Survey seismograph network in Hawaii fall into two categories: local earthquakes and tremor originating in the region of the Hawaiian Islands (usually within 100 km of at least one seismograph), and distant earthquakes originating more than 3,000 km from Hawaii. As an index of seismic activity at Hawaiian volcanoes, daily counts of earthquakes and minutes of tremor recorded by seismographs in Hawaii are listed in table 3. The earthquakes are separated into groups on the basis of region of origin as determined by analysis of records obtained daily at the Observatory (U, M, A, D, N, WP, MP). Earthquakes of magnitude 2.0 or greater are generally sufficiently well recorded to be located with greater precision; they are listed individually in table 4. Data on identifiable phases from distant earthquakes are listed in table 5.

Locations of the seismograph stations are shown on figure 1, and essential data pertaining to the stations were given in Summaries 25, 29, and 33.

Table 3.--Numbers of earthquakes and minutes of tremor recorded on seismographs U, M, A, D, N, WP, and MP around Kilauea caldera

Tremor is separated into three categories: deep, intermediate, and shallow, on the basis of relative amplitudes recorded by seismographs in the summit region. Unless otherwise stated, tremor is presumed to be associated with movement of magma within the central complex of Kilauea.

Earthquake categories are: Halemaumau rock slides, which are detected by the characteristic record they produce on the North Pit seismograph; shallow earthquakes in the Kilauea caldera region; shallow earthquakes along the SW. rift zone of Kilauea and the adjacent portion of the Kaoiki fault system; earthquakes along the eastern half of Kilauea's east rift zone (from the Pahoa seismograph); earthquakes from a source about 30 km beneath the Kilauea summit region; earthquakes from the upper east rift zone and the adjacent fault systems of Kilauea's south flank, and earthquakes from other regions: Kona, Mauna Kea, etc.

Date (1964)	Tremor (in minutes)			Earthquakes						
	Deep	Intermediate	Shallow	Halemaumau slides	Kilauea caldera	SW. rift and Kaoiki	Eastern east rift	Kilauea summit 30 km	Upper east rift	Others

Table 4.--Local earthquakes recorded by seismographs of the U.S. Geological Survey, July, August, and September, 1964

Entries for a given quake are: date, origin time (Hawaiian Standard Time), magnitude, depth, epicenter, and felt report. All earthquakes of magnitude 2.5 and larger, as well as many favorably located smaller ones, occurring on or near the island of Hawaii are included in the list.

In the following list, some origin times are followed only by "KM 30" and a statement of magnitude. These are all members of a continuing family of quakes noted also in other Summaries. The best mean focus for this group is beneath Halemaumau at a depth of 30 km (19°24.1' N., 155°17.1' W.).

In the following list a number of quakes are described as "Upper east rift" (see Summary 28). Further statistical study of this group which occurred in the swarm periods during July 1 to 6 and August 3 to 4 gives a mean epicenter 19°21.5' N., 155°14' W. about 2 km south of Aloi Crater at near-surface depth.

In Summary 24, "Kaoiki" was introduced as a symbol for listing any of a family of quakes with mean focus 19°24' N., 155°24' W., h=3 to 8 km. This symbol is used in the following list.

Date (1964)	Time			Magnitude	Depth (km)	Epicenter			Felt Report
	h	m	s			Lat. N.	Long. W.	Description	
July 1	10	43	09.5	4.5	5	19°18.8'	155°06.9'	10 km SE. of Makaopuhi seismometer.	Felt in Hilo, Kilauea summit, and Puna regions.

Table 5.--Distant earthquakes

Times are reported in Greenwich Civil Time which is 10 hours faster than Hawaiian Standard Time. A "c" following the time of P indicates compressional first motion; a "d" indicates dilatational first motion. Station symbols, locations, and instrumentation are presented in Summary 33 . Magnitudes calculated from the Hawaii seismograms are followed by (HVO). Location of epicenter, origin times, and focal depths, and magnitudes reported by other institutions are taken from "Preliminary Determination of Epicenters" published by the U.S. Coast and Geodetic Survey.

Chronological summary

Relative quiet reigned throughout the fourth quarter of 1964. Modest net inflation was registered for the period.

A few felt quakes were scattered through October, including one of magnitude 5.5 located offshore 83 km southwest of Milolii in South Kona. A spurt of inflationary tilt between October 17 and November 6 was indicated on the short-base tiltmeter. Total seismicity was very low.

October 20 marked the beginning of a month of increase in tremor; several minutes of short bursts and a few spasms of half-hour duration were recorded almost daily. A swarm of deep Kilauea quakes occurred on October 28-29; about 60 shocks were recorded, the largest of magnitude 3.5. Tilt drifted erratically during this time and until December 27. During November 11 through 14 a flurry of small shallow earthquakes took place along the lower east rift of Kilauea. More than 50 shocks were recorded at Pahoa, 3 of which were mildly felt near Kapoho.

An earthquake of magnitude near 5 occurred on December 2 at 22:29. It was reported felt on Oahu and Maui, as well as throughout Hawaii. It originated from a seismically active zone 30 km beneath Kilauea summit. An aftershock from the same source with magnitude 4 was felt on Hawaii on December 3 at 07:56 and a swarm of more than 300 smaller shocks from the same source, ranging in magnitude from 0.5 to 2.5, continued during the week following. Eight other felt quakes from various source areas were scattered through December. Scattered bursts of tremor continued and totaled nearly 700 minutes during December.

The lava lake in Alae Crater solidified completely by early October, as indicated by temperature gradient and releveling. All level stations on the lake showed subsidence after the end of September for the first time; stations above the liquid rose during each relevel period so long as any liquid remained. Twelve core holes were completed, and the drilling equipment was removed from the crater on December 16.

A level line and a loop of closure were established on the upper 5 miles of slope to the north edge of Mokuaweoweo caldera on Mauna Loa. Releveling of this line and loop will yield a measure of summit inflation and deflation. It is logistically impossible to operate the water-level tiltmeter surveys around the remote summit of the big volcano.

R. W. Decker returned to Dartmouth College in December after completing 6 months of special studies of a program for monitoring structural events at Kilauea.

Mr. Rodrigo Saenz R., a scientist from the government of Costa Rica, has joined the staff at the Hawaiian Volcano Observatory to learn methods of study that have proved useful here. Mr. Saenz will conduct monitoring studies of Cost Rican volcanoes when he returns to Costa Rica.

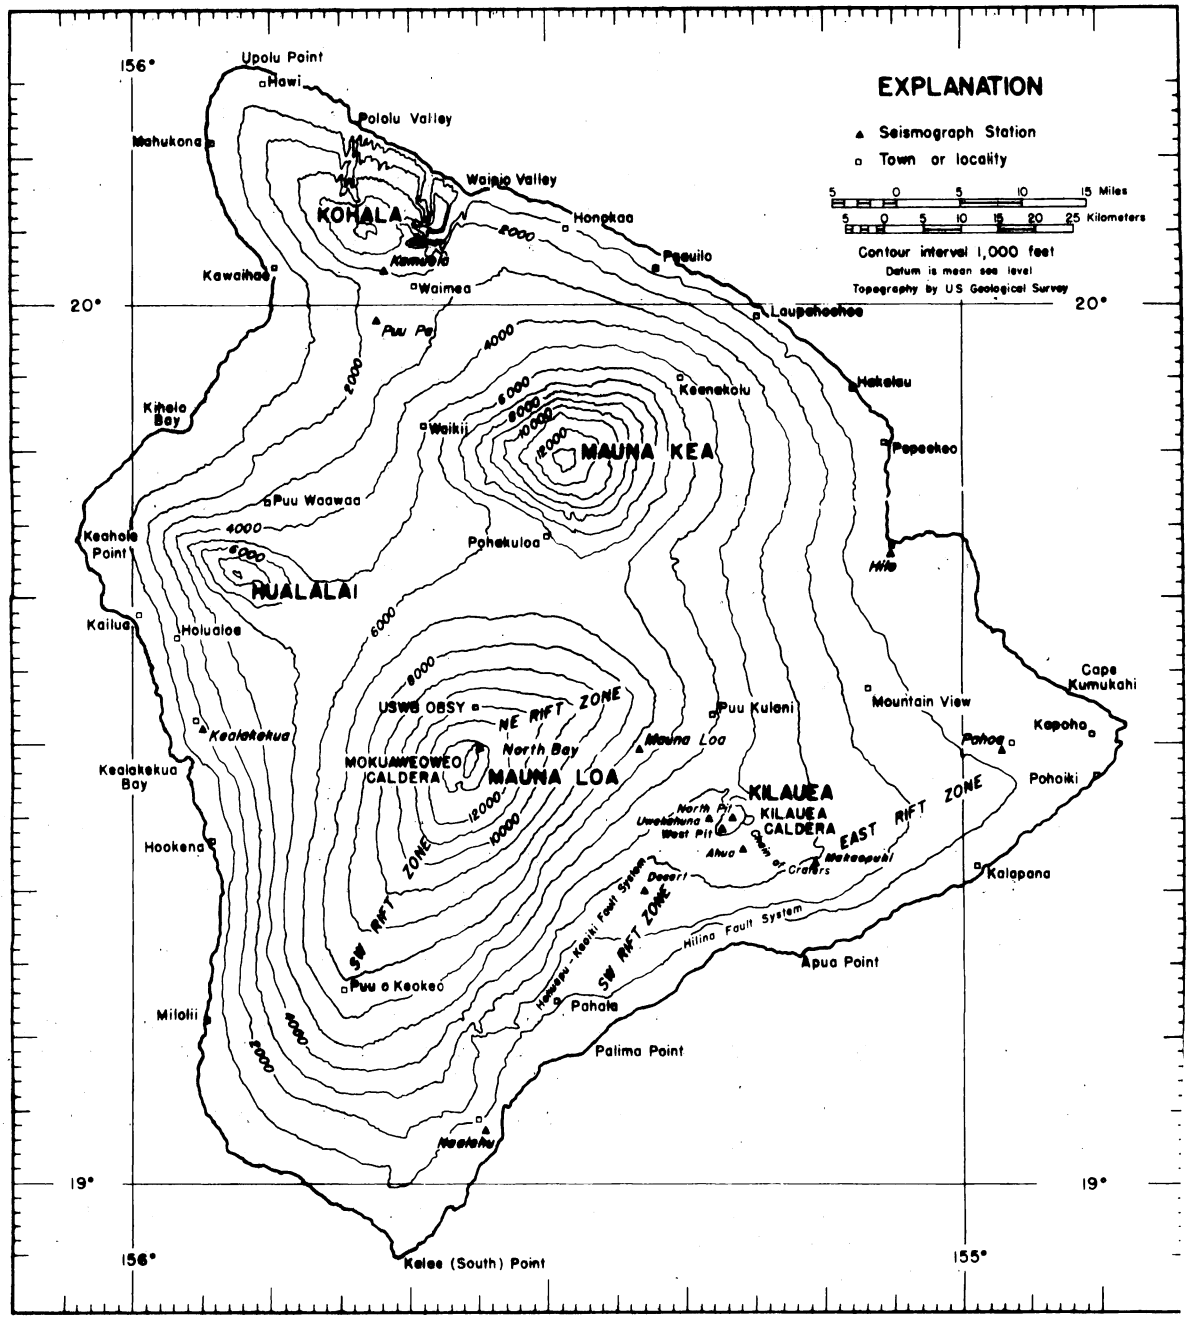

Figure 1.--Map of the island of Hawaii showing seismograph stations operated by the Geological Survey and localities mentioned in the text. Epicenters of local earthquakes are given in terms of geographic coordinates, which are indicated at the edges of the map.

Tilting of the ground around Kilauea caldera.--Tilting of the ground around the summit of Kilauea is monitored daily by a short-base water-tube tiltmeter in Uwekahuna Vault, and at irregular intervals it is measured on a regional scale by means of a network of field tilt bases and a portable water-tube tiltmeter. The attitude of the ground surface at each tilt base is reported in terms of north-south and east-west tilt coordinates. Both coordinates at each station were set equal to 500 when measurements at that station were begun. Increasing tilt coordinates correspond to northward and eastward tilting of the earth's surface; that is, to a relative subsidence toward the north and east. A one-unit change in coordinate corresponds to a tilting of 1 microradian (1 mm per km) in the direction indicated.

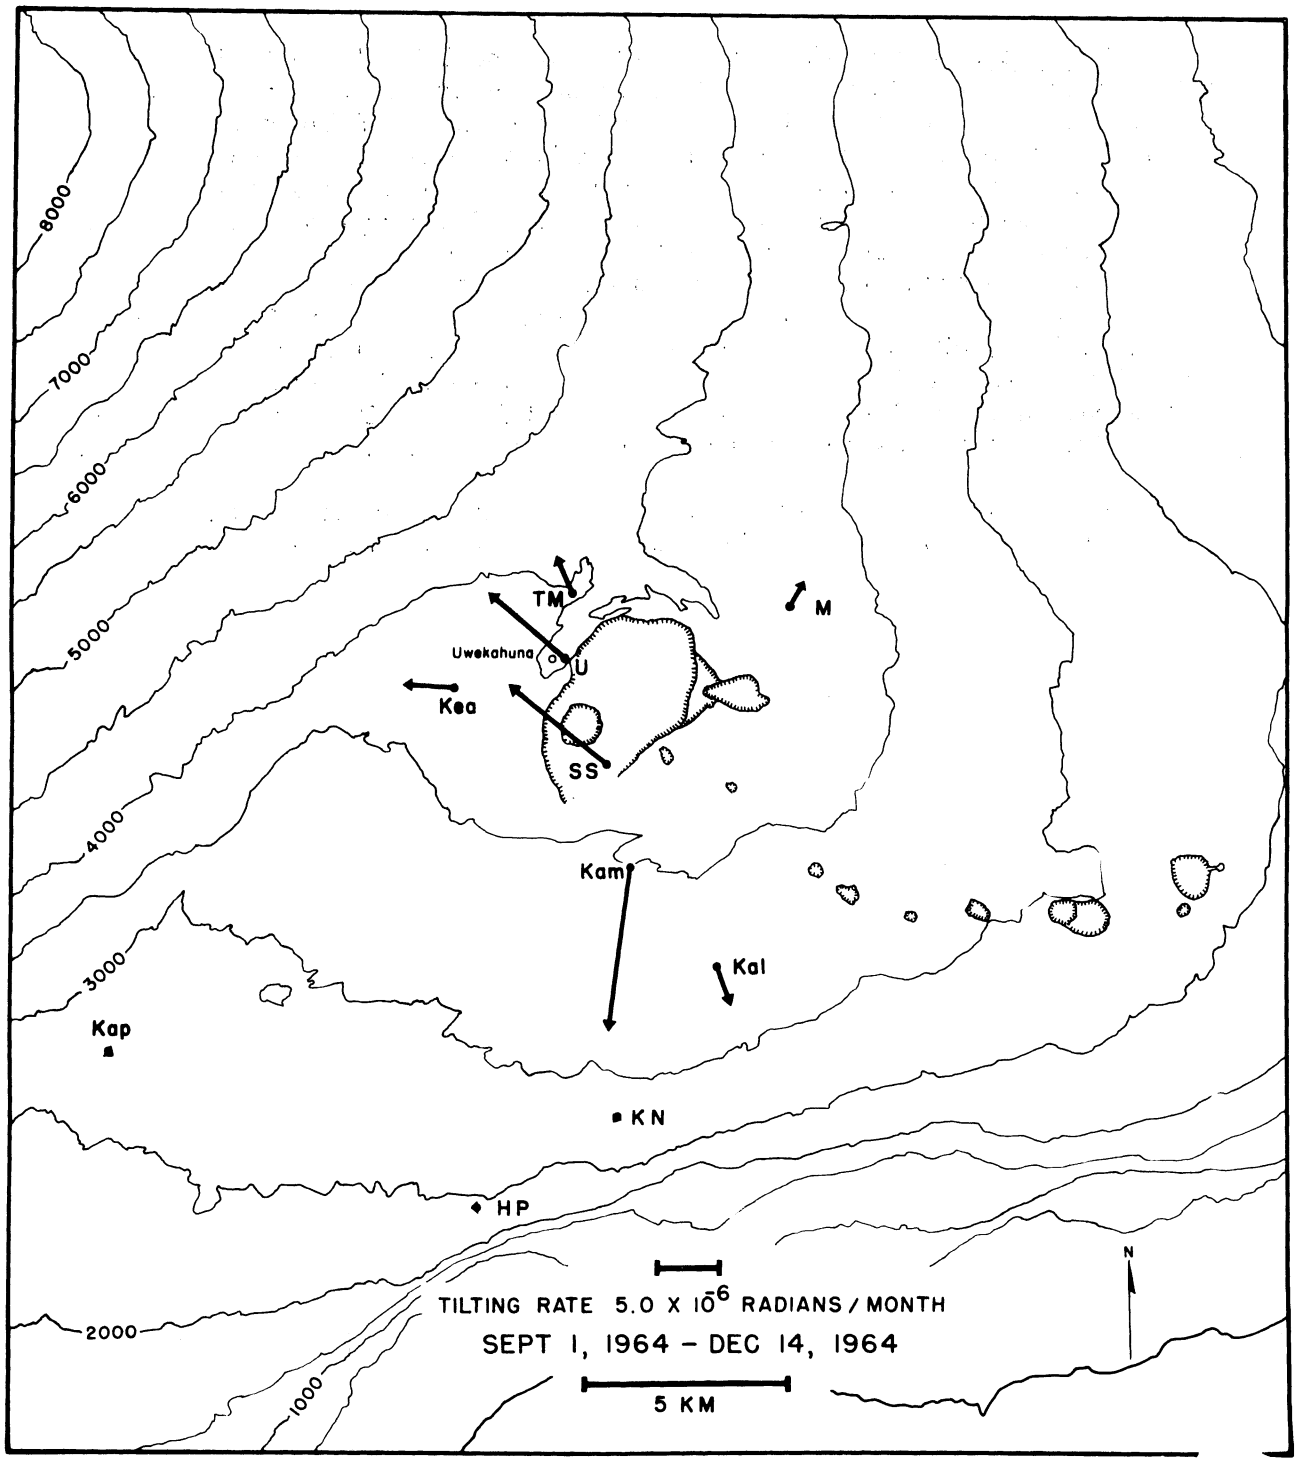

Figure 2.--Tilting of the ground around Kilauea caldera, Sept. 1-Dec. 14, 1964. The vector depicting tilting at a given tilt base points in the direction of maximum relative subsidence and has a length proportional to the rate of tilting during the measurement interval. Closed circles represent field tilt bases; open circles, short-base water-tube tiltmeters.

Seismic summary.--Events recorded by the U.S. Geological Survey seismograph network in Hawaii fall into two categories: local earthquakes and tremor originating in the region of the Hawaiian Islands (usually within 100 km of at least one seismograph), and distant earthquakes originating more than 3,000 km from Hawaii. As an index of seismic activity at Hawaiian volcanoes, daily counts of earthquakes and minutes of tremor recorded by seismographs in Hawaii are listed in table 3. The earthquakes are separated into groups on the basis of region of origin as determined by analysis of records obtained daily at the Observatory (U, M, A, D, N, WP, MP). Earthquakes of magnitude 2.0 or greater are generally sufficiently well recorded to be located with greater precision; they are listed individually in table 4. Data on identifiable phases from distant earthquakes are listed in table 5.

Locations of the seismograph stations are shown on figure 1, and essential data pertaining to the stations are listed in table 6, Summary 33.

Table 3.--Numbers of earthquakes and minutes of tremor recorded on seismographs U, M, A, D, N, WP, and MP around Kilauea caldera

Tremor is separated into three categories: deep, intermediate, and shallow, on the basis of relative amplitudes recorded by seismographs in the summit region. Unless otherwise stated, tremor is presumed to be associated with movement of magma within the central complex of Kilauea.

Earthquake categories are: Halemaumau rock slides, which are detected by the characteristic record they produce on the North Pit seismograph; shallow earthquakes in the Kilauea caldera region; shallow earthquakes along the SW. rift zone of Kilauea and the adjacent portion of the Kaoiki fault system; earthquakes along the eastern half of Kilauea's east rift zone (from the Pahoa seismograph); earthquakes from a source about 30 km beneath the Kilauea summit region; earthquakes from the upper east rift zone and the adjacent fault systems of Kilauea's south flank, and earthquakes from other regions: Kona, Mauna Kea, etc.

Date (1964)	Tremor (in minutes)			Earthquakes

Table 4.--Local earthquakes recorded by seismographs of the U.S. Geological Survey, October, November, and December, 1964

Entries for a given quake are: date, origin time (Hawaiian Standard Time), magnitude, depth, epicenter, and felt report. All earthquakes of magnitude 2.5 and larger, as well as many favorably located smaller ones, occurring on or near the island of Hawaii are included in the list.

In the following list, some origin times are followed only by "KM 30" and a statement of magnitude. These are all members of a continuing family of quakes noted also in other Summaries. The best mean focus for this group is beneath Halemaumau at a depth of 30 km (19°24.1' N., 155°17.1' W.).

The mean focus of the magnitude 6.1 Kaoiki fault system earthquake of June 27, 1962, and its aftershocks is 19°24' N., 155°25' W., at a depth of 3-8 km. This focus has been abbreviated "Kaoiki."

Table 5.--Distant earthquakes

Times are reported in Greenwich Civil Time which is 10 hours faster than Hawaiian Standard Time. A "c" following the time of P indicates compressional first motion; a "d" indicates dilatational first motion. Station symbols, locations, and instrumentation are presented in table 6. Magnitudes calculated from the Hawaii seismograms are followed by (HVO). Location of epicenter, origin time, focal depth, and magnitudes reported by other institutions are taken from "Preliminary Determination of Epicenters" published by the U.S. Coast and Geodetic Survey.

C&GS card 105-64:
21:30:58.8
23.3° S., 179.9° W.
South of Fiji Islands
h about 547 km
Magnitude 5.2 (CGS).

The following persons or agencies reported "felt" earthquakes during the 4th quarter, 1964. Their assistance is gratefully acknowledged.

Mauna Loa summit area

Mr. W. Francis
Mr. R. Decker
Mr. A. Yamamoto

Kilauea summit area

Mrs. C. Wentworth
Mr. A. Yamamoto
Mr. R. Decker
Mr. D. Peck
Mrs. B. Sumner
Mr. and Mrs. G. Yong
Mr. and Mrs. J. Hanson
Miss M. English
Mrs. M. Gorder
Mr. H. Mist

North Hawaii

Mr. R. Eklund
Mrs. P. Richards
Mr. A. Walker
Mr. Y. Kojima

Kona

Miss A. Greenwell
Mr. R. Apple
Mr. M. Sutherlund
Miss N. Wallace
Mrs. C. Higashihara

Kau

Mrs. Hunter
Mrs. A. Paiva
Mrs. P. Billings
Rev. D. Thompson
Mrs. Carvalho
Mr. W. Meinecke
Mr. E. Ross
Mrs. C. Ashton

Hilo region

Miss E. Patton
Mr. J. Bryan
Mrs. B. Shaffer
Hilo Police Station
Civil Defense Office
Mr. H. Pierce
Mr. J. Chang
Mr. Walker
Mr. H. Lewis
Mr. E. Crumb
Mr. S. Ho
Mr. R. Baldwin

Puna

Mr. R. Edwards
Mr. H. Warner
Mr. K. Kimura
Mr. C. Guerino
Mr. E. Ross
Mr. R. Williamson
