

DISCUSSION

This acoustic backscatter map of the Monterey Canyon and Vicinity map area in central California was generated from acoustic backscatter data collected by California State University, Monterey Bay (CSUMB), Monterey Bay Aquarium Research Institute (MBARI), and the U.S. Geological Survey (USGS) (Fig. 1). Mapping was completed between 1998 and 2014 using a combination of 300-kHz Simrad EK60 and 200-kHz Simrad EK60 125 multibeam echosounders, as well as 224-kHz and 468-kHz SEASWATHplus phase-differencing sidescan sonars. These mapping missions combined to collect acoustic backscatter data from about the 10-m to both to beyond the limit of California's State Waters cover that the California's State Waters limit, which generally is 3 nautical miles from shore, extends farther offshore between Santa Cruz and Monterey, so that it encompasses all of Monterey Bay.

During the MBARI mapping mission in 1998, an Applied Acoustic POS MV (Position and Orientation System for Marine Vessels) was used to accurately position the vessel during data collection, and it also accounted for vessel motion with an optional input from a kinematic differential global positioning system (DGPS) system. Soundings were corrected for variations in water-column sound velocity using data from Seafloor CTD (conductivity, temperature, and depth) and Sippican T5 expendable bathythermograph. The USGS downloaded the original MBARI survey line file from the National Center for Environmental Information's Environmental Services (National Center for Environmental Information, 2015) and processed them using MB-Systems.

During the CSUMB mapping missions in 2008 and 2009, an Applanix POS MV was used to accurately position the vessels during data collection, and it also accounted for vessel motion such as heave, pitch, and roll (position accuracy: 0.2 m; pitch, roll, and heading accuracy: 0.02°; heave accuracy: 0.5 m; roll accuracy: 0.5 m) from a NovAtel 205H GPS receiver (NAV). Kinetic GPS (KGPS) attitude data were used to account for tide-cycle fluctuations, and sound-velocity profiles were collected with an Applied Acoustic SVP (Sound Velocity Profiler) model velocimeter. Soundings were corrected for vessel motion using the Applanix POS MV data, for variations in water-column sound velocity using the AM SVPlus data, and for variations in water height (tides) using vertical position data from the GPS receiver. Multi-beam backscatter data were processed using Cocooner. Within Cocooner, the backscatter intensities were radiometrically corrected (including despiking and angle-varying gain adjustments), and the position of each acoustic sample was geometrically corrected for slant range on a line-by-line basis. After the files were corrected, they were mosaicked into 1- or 2-m-resolution images. Overlap between parallel lines was resolved using a priority table whose values were based on the distance of each sample from the ship track, with the samples that were closest to and furthest from the ship track being given the lowest priority. An anti-aliasing algorithm was also applied. The mosaics were then exported as georeferenced TIFF images, imported into a geographic information system (GIS), and converted to GRIDs at 2-m resolution.

During the USGS mapping missions in 2009 and 2014, GPS data with real-time-kinematic corrections were combined with measurements of vessel motion (heave, pitch, and roll) in a CalStarops F10 attitude-and-position system (2009) and an Applanix POS MV (2014) to produce a high-precision vessel-attitude packet. This packet was transmitted to the acquisition software in real time and combined with instantaneous sound-velocity measurements at the transducer head before each ping. The returned samples were projected to the seafloor using a ray-tracing algorithm that works with previously measured sound-velocity profiles. Statistical filters were applied to discriminate seafloor returns (contours) from unintended targets in the water column (fish and other organisms, 2010). Further sounding cleaning was completed in Caris HIPS and SIPS software. Finally, the soundings were converted into 2-m-resolution bathymetric-raster-mosaic grids.

The backscatter data collected by CSUMB and USGS were processed using USGS software (D.P. Finlayson, 2011, written comments) that normalizes for non-varying signal loss and beam diversity differences. Thus, the pre-16-bit backscatter data were gain-normalized to enhance the backscatter of the SEASWATHplus system. The resulting normalized-amplitude values were rescaled to 16-bit and gridded into GeoTIFFs using GRID Processor Software, then imported into a GIS and converted to GRIDs.

The acoustic backscatter imagery from each different mapping system and processing method were merged into their own individual grids. The shallowest 100-m and CSUMB acoustic backscatter grids have a spatial resolution of 2 m, whereas the deeper MBARI grid has a 5-m resolution. These individual grids, which cover different areas, were displayed in a GIS to create this map, in which brighter tones indicate higher backscatter intensity, and darker tones indicate lower backscatter intensity. The intensity represents a complex interaction between the acoustic pulse and the seafloor, as well as characteristics within the shallow subsurface, providing an indication of seafloor texture and composition. Backscatter intensity depends on the acoustic source level, the frequency used to image the seafloor, the grazing angle, the composition and character of the seafloor, including grain size, water content, bulk density, and seafloor roughness, and some biological cover. Harder and rougher bottom types such as rocky outcrops or coarse sediment typically return stronger intensities (high backscatter, lighter tones), whereas softer bottom types such as fine sediment return weaker intensities (low backscatter, darker tones). Note that the regular patterns and straight lines that are apparent within the map area are data-collection and processing artifacts. Data gaps in the deeper section of Monterey Canyon (in the southeast corner of the map area) are where backscatter soundings are too dense, which results in no data being found within a 5-m grid cell.

Bathymetric contours were generated from modified 2- and 5-m-resolution bathymetric surfaces (see sheets 2 of this report). Contours were generated at 10-m intervals for water depths shallower than 100 m, at 50-m intervals for water depths between 100 and 200 m, and at 200-m intervals in water depths deeper than 200 m. The original surfaces were smoothed using the Focal Mean tool in ArcGIS and a circular neighborhood that has a radius of between 20 and 30 m (depending on the area). The contours were generated from these smoothed surfaces using the Spatial Analyst Contour tool in ArcGIS. The near continuous contour segments were connected, small gaps were filled, and isolated island polygons were excluded from the final output. The contours were then clipped to the boundary of the map area.

The reference image was generated by applying the same illumination (azimuth of 300° and 10-m 40° above the horizon) to 2-m-resolution topographic-lidar data from National Oceanic and Atmospheric Administration (NOAA) Office for Coastal Management's Digital Coast (available at <http://www.cdc.noaa.gov/digitalcoast/data-continental/>) and to 10-m-resolution topographic-lidar data from the U.S. Geological Survey's National Elevation Dataset (available at <http://ned.usgs.gov/>).

EXPLANATION

Backscatter intensity
High
Low

Area of "no data"—Areas near shoreline not mapped owing to insufficient high-resolution seafloor mapping data; areas beyond limit of California's State Waters were not mapped as part of California Seafloor Mapping Program

Limit of California's State Waters

Bathymetric contour (in meters)—Derived from modified 2- and 5-m-resolution bathymetry grids. Contour intervals: 1–100 m water depth, 10 m; 100–200 m water depth, 50 m; >200 m water depth, 200 m.

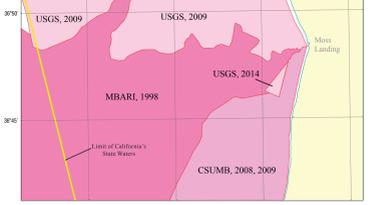

Figure 1. Map showing areas of multibeam echosounder and bathymetric sidescan surveys (pink shading) and sidescan topographic-lidar surveys (yellow shading). Also shown are data collecting agencies (CSUMB, California State University, Monterey Bay; Seafloor Mapping Lab, MBARI, Monterey Bay Aquarium Research Institute; USGS, U.S. Geological Survey) and dates of surveys if known. Yellow line shows limit of California's State Waters.

Celex elevation data from National Oceanic and Atmospheric Administration (NOAA) Office for Coastal Management's Digital Coast (available at <http://www.ngd.noaa.gov/mgs/bathyviewer/>) and from U.S. Geological Survey's National Elevation Dataset (available at <http://ned.usgs.gov/>). California's State Waters limit from NOAA Office of Coast Survey.
