Summary

PL_isopach -- Spatial database for isopach map of the Patience Lake Member of the Prairie Evaporite, Elk Point Group, in the Elk Point Basin, Canada and U.S. (in Esri file geodatabase feature class format).

The spatial database was created for use in a geographic information system (GIS) as part of a global potash resource assessment by the U.S. Geological Survey.

Description

The Elk Point Basin is an evaporite basin of Middle Devonian age that contains a significant portion of the world's potash resources. Potash-bearing salt is concentrated in the upper 100 meters of the Prairie Evaporite in the Patience Lake, Belle Plaine, White Bear, and Esterhazy Members. Known potash mineralization is concentrated in the southeastern portion of the Elk Point Basin mainly in Saskatchewan and extending short distances into adjacent parts of Alberta, Manitoba, North Dakota, and Montana.

Permissive tracts were delineated by the extent of each member of the Prairie Evaporite where the member is at least 1 meter in thickness and less than 3 kilometers from the surface.

Potash resources were assessed for each tract using a method based on an enhanced geometric analysis of the likely spatial distribution of potash mineralization. We used Monte Carlo simulations to estimate missing or incomplete variables such as density, average grade, and geologic loss due to salt dissolution to calculate the distribution and abundance of estimated undiscovered potash (as K₂O). Potash grades were calculated using both historic (1950s and 1960s) and recent (2007–2011) drill hole analyses. The mean estimated undiscovered K₂O resource (which includes sylvite and carnallite) in these tracts is 864 billion metric tons.

Credits

Mark Cocker interpreted the data and is responsible for the scientific content.

Pamela Dunlap processed the digital data, built the spatial database, and generated volume data.

Deborah A. Briggs rectified scanned images of paper maps to produce georectified TIFF images (GeoTIFFs) for use in a GIS. She also digitized initial areas for extent of carnallite.

Leila Gass digitized areas of known salt solutioning from the GeoTIFF images and assisted in digitizing revisions to isopachs.

Use limitations

None. The U.S. Geological Survey (USGS) provides these geographic data "as is." The USGS makes no guarantee or warranty concerning the accuracy of information contained in the geographic data. The USGS further makes no warranties, either expressed or implied as to any other matter whatsoever, including, without limitation, the condition of the product, or its fitness for any particular purpose. The burden for determining fitness for use lies entirely with the user. Although these data have been processed successfully on computers of the USGS, no warranty, expressed or implied, is made by the USGS regarding the use of these data on any other system, nor does the fact of distribution constitute or imply such warranty.

Lineage ►

Lineage statement

Total thickness of each member of the Prairie Evaporite was determined from well and drill-hole data in the feature class ElkPt_thickness, augmented by data derived from Fuzesy (1982) and Great Northern Railway Company (1965). These data were used to construct isopach maps of each member (see the feature classes BP_isopach, ES_isopach, PL_isopach, and WB_isopach) where overburden was less than 3 km in depth.

Process step ►

When the process occurred 2011-11-14 00:00:00

Description

Several steps were taken to process the data to create the isopach maps. Initially, data from drill holes and wells in Canada were used to create a continuous raster surface (using the natural neighbors interpolation algorithm in ArcGIS 9.3) from which contours (line features) were computer generated at 2-m intervals of thickness (starting at 1 m). Additional data from hand-drawn isopach maps of potash-bearing units in the United States were then digitized and incorporated into the existing datasets of thickness contours for Canada. Isopachs were truncated at the southern margin (in the U.S.) where overburden exceeded 3 km in depth. These line features were converted to polygon features which were then attributed for minimum, maximum, and average thickness for each member of the Prairie Evaporite. Areas of known salt solutioning and areas representing thickness less than 1 m were removed; the resultant isopach map datasets were proofed against the drill-hole and well dataset, and areas of salt solutioning were manually revised to exclude data points where thickness was greater than or equal to 1 m.
