RECLASSIFICATION AUTHORIZATION

In accordance with the authority delegated to me by memorandum from the General Manager, dated December 6, 1948, subject, "Security Procedures and Policies relating to the Domestic Raw Materials Program," and based on criteria for determining classification, as outlined in Appendix A attached thereto, the document listed below is reclassified as indicated.

TRACE ELEMENTS RECONNAISSANCE IN THE CANDLE CREEK AREA, FAIRHAVEN DISTRICT, SEWARD PENINSULA, ALASKA

By M. A. Gault

ABSTRACT

A black cubic mineral, questionably identified as uraninite-thorianite, is abundant in one of two significantly radioactive placer samples obtained prior to 1945 from the Candle Creek area on the Seward Peninsula. Only four of the 16 concentrate samples collected during the field season of 1945 from this area contain more than 0.01 percent equivalent uranium. Although mineralogical study of the samples collected in 1945 failed to isolate the radioactive mineral grains, additional reconnaissance in the Candle Creek area appears warranted.

INTRODUCTION

Preliminary radioactivity tests were made in the spring of 1945 on a small collection of placer samples obtained from the Candle Creek area, Seward Peninsula, Alaska, during earlier Geological Survey investigations. One sample contained more than 5 percent equivalent uranium, hereafter abbreviated to E. U., and a second sample contained 0.049 percent E. U. On the basis of

these results, the writer spent the last week of July 1945 in the
Candle Creek area collecting a representative group of samples from the placer workings along Candle Creek and its principal tributaries for the purpose of determining the advisability of a more detailed search for radioactive mineral deposits in the area.

LOCATION

The Candle Creek area is a part of the Fairhaven district in the northeastern corner of the Seward Peninsula (fig. 1). Candle Creek flows northeast and joins the Kivalik River at the site of the town of Candle. The Kivalik River continues north beyond Candle for 6 miles to the head of Kivalik Bay, an inlet of Kotzebue Sound which in turn opens into the Arctic Ocean.

Candle is the chief settlement and source of supply for the placer mines in this area. It is about 140 airline miles northeast of Nome. The population is small and consists mainly of Natives, some white Government workers, and employees of the Arctic Circle Exploration Company. The latter company is the main placer-mining outfit in the area and has been operating since 1935. The town possesses two small landing fields, and many supplies are brought in by plane from Fairbanks. Small boats bring in supplies through Kotzebue Sound during the months of July and August.

A road leads up Candle Creek for a distance of about 5 miles from the town.

GEOLOGY AND PLACER MINING

The general geology of the Fairhaven district has been described by Hoffit. Along Candle Creek the bedrock is predominantly a mica.
schist cut by small quartz stringers. Small dikes and sills of rhyolite also cut the schist, and a few are exposed in the placer workings on the bench ground. A gneissic intrusive is mapped near the head of Potato Creek.

Placer mining in the Candle Creek area has been carried on since 1901, when a stampede followed the discovery of placer gold on Jump Creek and the rich spots along Candle Creek were worked by rocker. Gold-bearing gravels have been mined or are known along the lower 5 miles of Candle Creek; along Jump and Patterson Creeks, tributaries to Candle Creek from the west (fig. 1); and in the Kisulik River flats north of the town of Candle. Both creek and bench deposits occur along Candle Creek and its tributaries. The creek gravels are worked by dredge, and the bench ground is sluiced with hydraulic giants. The creek gravels are 12 to 18 feet thick and are covered by 10 to 20 feet of tundra. The bench gravels are 4 to 10 feet thick and are overlain by 5 to 10 feet of tundra. All of the ground is permanently frozen a few feet below the surface.

RADIOACTIVITY TESTS

Samples obtained prior to 1965 field investigation

Seven of the samples in the Alaskan concentrate collection that were tested for radioactivity in the winter of 1944-45 are from the Candle Creek area. As the data on these samples are scattered in various parts of the report on that work and are not
complete, the information is assembled herein. One sample in that collection, no. 327, was not listed in the preliminary report. Some doubt exists that sample no. 377 is actually from the Candle Creek area, as a Windy Creek is not shown on any of the maps of the area. The exact locations from which sample nos. 208 and 209 were obtained are uncertain, although both are from the Candle Creek area. The majority of these samples were obtained from placer mines operating in 1917 by G. L. Harrington of the Geological Survey while he was engaged in investigations farther south. The data on these samples are given in table 1.

Samples obtained in 1945

Data on the 16 samples collected in the Candle Creek area in 1945 are presented in table 2. The sampling was designed to include:

1) All types of deposits over as wide an area as possible.
2) The various stages in the different recovery methods used in the placer-mining operations.

Of the 16 samples, 10 are from the main valley of Candle Creek, 3 are from the Kivalik River flats below Candle, and 3 are from tributaries of Candle Creek (fig. 1). The 10 samples from Candle
Creek were collected from various claims beginning at claim 6-Below
and ending at claim 19-Above at the mouth of Patterson Creek. The
location of the dredge concentrate sample (no. 1115), which is a
composite of concentrates from claims 13- to 19-Above, is not
plotted on the map. The dredge operating in 1945 was just below
the mouth of Patterson Creek and was working upstream.

Results and conclusions

The U. U. content of the samples collected in 1945 ranges from
0.001 to 0.025 percent. Radioactivity exceeds 0.01 percent U. U.
in only four samples. The minimum concentration ratios for these
four samples with respect to the original gravels range between 7,500
and 25,000 to 1 by volume. The best recovery per cubic yard ob-
tained in sampling was approximately three-fifths of a pound of con-
centrate containing 0.025 percent U. U.

Heavy-mineral studies of several samples collected in 1945
failed to isolate the radioactive grains, and the identification of
the mineral or minerals carrying the radioactive elements is still
uncertain. Nevertheless, mineralogical examination of sample
no. 371 made by Larsen for Harder and Reed's report / showed that

/ Harder, J. O., and Reed, J. C., op. cit., appendix, p. 1,
1945.

a highly radioactive, black cubic mineral, questionably identified
as uraninite, makes up the larger part of the active portion of
the concentrate. Zircon and sphene, both of which may carry radio-
active elements, are also present. The black cubic mineral also occurs in samples from the Sweepstakes Creek area of the Koyuk basin about 30 miles south of Candle. Field work subsequent to the 1945 investigations has indicated that this mineral is widely distributed in the eastern part of the Seward Peninsula.

---

No evidence of the bedrock source of the radioactive materials present in the Candle Creek placer concentrates was obtained during the brief field investigation.

RECOMMENDATIONS

The sampling in the Candle Creek area, although not extensive, included all of the mining operations active at the time. If an opportunity occurs, further sampling on Potato Creek probably is warranted. A small area of schistose or gneissic rock mapped near the head of Potato Creek and believed to be an altered acidic intrusive rock should also be sampled or checked for radioactivity by field traversing with a Geiger-Mueller counter. Additional study in
the Potato Creek area might yield information on the bedrock source of the radioactive material.

After the completion of the Geological Survey's 1945 field work in the Candle Creek area, Fritz Reinard is said to have begun mining with a 3-man dozer-hydraulic outfit on Mud Creek near Candle. / Stewart, B. D., Biennial report of the inspector of mines, Territory of Alaska, 1945-46.

Samples from this new site have not been requested for radioactivity tests.

Older sites of mining from which no samples have been obtained and which could probably be reached from Candle include:

1) The placers near the mouth of Alder Creek on the coast west of Kwalik Bay that have not been worked since 1903

2) The placers of Glacier Creek and Gold Run, western tributaries of the Kwalik River, where the last recorded mining was in 1927 and 1929.

Further mineralogical work is needed on the samples that are available. These laboratory studies are being carried on and will be incorporated in a summary report on the distribution of the radioactive black cubic mineral in the eastern Seward Peninsula.
