QUALITY OF WATER IN THE RED RIVER ALLUVIAL AQUIFER, SHREVEPORT,
TO THE MOUTH OF THE BLACK RIVER, LOUISIANA

By A. H. Ludwig

ABSTRACT

Chemical analyses of water samples from 296 wells in the Red River alluvial aquifer indicate that the ground water in the valley is generally hard (more than 120 milligrams per liter) and has a high iron concentration (greater than 6,000 micrograms per liter). The predominant ions found in the water were calcium and bicarbonate. However, in places in the vicinity of Natchitoches, saline water, probably from underlying formations, has infiltrated the aquifer and sodium and chloride are the principal constituents.

INTRODUCTION

The navigation plans of the U.S. Army Corps of Engineers call for a series of locks and dams on the Red River between the mouth of Black River and Shreveport, La. (fig. 1). The U.S. Geological Survey, in cooperation with the Corps of Engineers, is conducting an investigation to determine the potential effects on ground-water levels of changes in stream stage that will be caused by the proposed navigation structures. The investigation also includes the determination of the existing chemical quality of water in the alluvial aquifer. The effects on ground-water levels are discussed in separate reports.

Changes in ground-water quality may also occur as a result of the proposed construction. As an aid in evaluating possible changes, chemical data were collected to document the existing quality of water in the Red River alluvial aquifer. The purpose of this report is to release data collected during the initial phase of the project on the quality of water in the alluvial aquifer.

DATA COLLECTION

Ground-water samples were collected from 296 wells in the alluvial aquifer. Most of the data were collected from August 1968 to July 1973 in connection with the current navigation study. The report also contains selected water-quality data collected prior to 1968 by the Geological Survey as part of parish ground-water appraisal studies. The well locations are shown in figure 2, sheets 1 through 6. Each sheet presents chemical data on a separate lock and dam area under investigation.

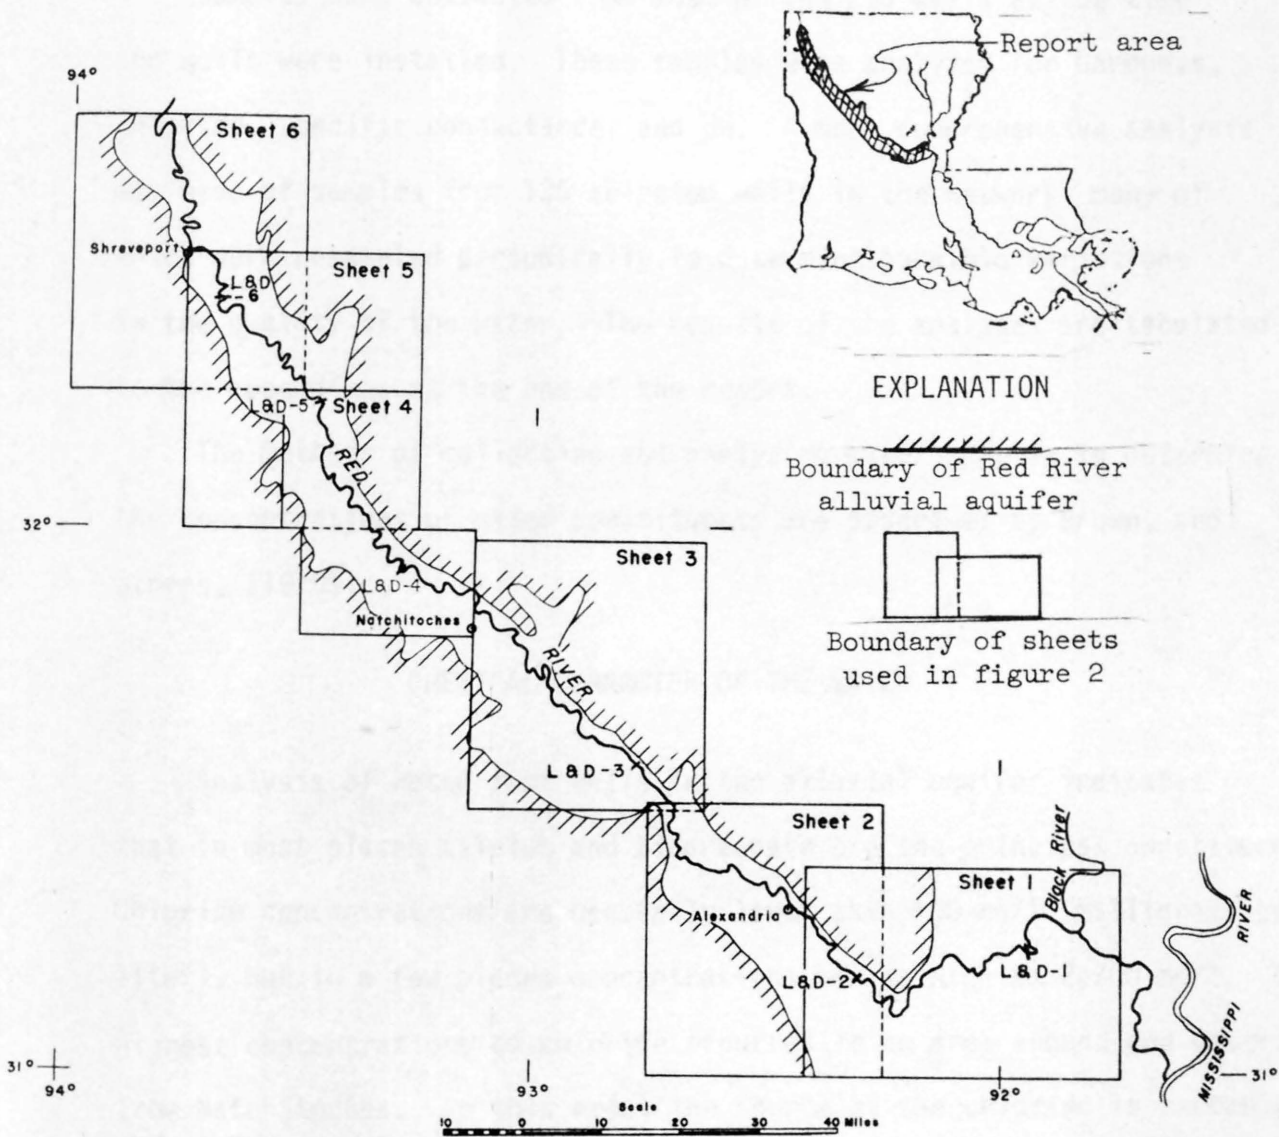

Figure 1.—Location of report area.

Samples were collected from most of the 296 wells at the time the wells were installed. These samples were analyzed for hardness, chloride, specific conductance, and pH. A more comprehensive analysis was made of samples from 125 selected wells in the network, many of which were resampled periodically to determine possible variations in the quality of the water. The results of the analyses are tabulated in the appendixes at the end of the report.

The methods of collecting and analyzing water samples to determine the concentrations of major constituents are described by Brown, and others, (1970).

CHEMICAL CHARACTER OF THE WATER

Analysis of water from wells in the alluvial aquifer indicates that in most places calcium and bicarbonate are the principal constituents. Chloride concentrations are generally lower than 100 mg/l (milligrams per liter), but in a few places concentrations are as high as 2,700 mg/l. The highest concentrations of chloride occurred in an area around and upstream from Natchitoches. In this area, the source of the chloride is probably upward leakage of water of high salinity from known underlying saline water-bearing formations. Hardness ranges from 5 to 1,900 mg/l and averages about 500 mg/l for the waters sampled. The dissolved iron concentration of the water ranges from 30 to 59,000 ug/l (micrograms per liter) (0.03 to 59 mg/l). The median iron concentration is about 6,000 ug/l (6 mg/l).

Figure 2 shows a graphic representation of selected analyses. The concentration of a constituent, or group of constituents, is shown by the length of a branch of the diagram. Those constituents which comprise more than 50 percent of the cations and anions in a sample determine the type of the water (Hem, 1970, p. 237). For example, in figure 2, sheet 1, the diagram for well R-734 shows that the water at that location is a calcium bicarbonate type. Water from the nearby well R-959 is a mixed type; that is, it contains a significant percentage of sodium and chloride as well as calcium and bicarbonate. This scheme provides a visual means of comparing the quality of water from place to place.

Analyses of samples collected from February 1972 to June 1973 of a group of wells (indicated by asterisks in the appendixes) indicate that little change in major constituents occurred during this period. However, locally, changes in chemical quality have occurred during a period of several years. Additional long-term data are needed to determine the significance of these variations in the concentrations of constituents.

Several wells in the upland terrace, adjacent to the Red River Valley, were sampled as part of the data-collection program for this investigation. Results of the analyses are shown in the appendixes. The analysis of samples from three of these wells R-849, AV-227, RR-199 show that the water is very dilute and contains 120 mg/l or less of total dissolved solids. In contrast, the dissolved-solids concentration of water samples from the alluvial aquifer is generally greater than 200 mg/l and averages about 500 mg/l.

More detailed information is needed near the proposed lock and dam sites to adequately define the quality of water in these areas. Therefore, the study of the quality of water in the alluvial aquifer will be continued. Specifically, the objective of the continuing study will be to define possible anomolous areas of water quality and to determine the significance of time variations in the chemical quality of the water. The data collected as part of the continuing study will be included in a future report by the Geological Survey.

APPENDIX B
BOSSIER PARISH

NOTE.--Three consecutive pages are required for each complete analysis and are indicated thus: B-2, B-2-Continued, and B-2-Continued. Well numbers are repeated on each page.

The following footnotes are used in this Appendix:

¹Sequence number 01 refers to samples collected from USGS wells, 02 refers to samples collected from SCS piezometers located adjacent to USGS wells.

²Divide micrograms per liter (ug/l) by 1,000 to obtain milligrams per liter (mg/l).

*Analysis referred to in text.

APPENDIX C
CADDO PARISH

NOTE.--Three consecutive pages are required for each complete analysis and are indicated thus: C-2, C-2-Continued, and C-2-Continued. Well numbers are repeated on each page.

The following footnotes are used in this Appendix:

¹Sequence number 01 refers to samples collected from USGS wells, 02 refers to samples collected from SCS piezometers located adjacent to USGS wells.

²Divide micrograms per liter (ug/l) by 1,000 to obtain milligrams per liter (mg/l).

*Analysis referred to in text.

APPENDIX D
CATAHOULA PARISH

NOTE.--Three consecutive pages are required for each complete analysis and are indicated thus: D-2, D-2-Continued, and D-2-Continued. Well numbers are repeated on each page.

The following footnotes are used in this Appendix:

¹Sequence number 01 refers to samples collected from USGS wells, 02 refers to samples collected from SCS piezometers located adjacent to USGS wells.

²Divide micrograms per liter (ug/l) by 1,000 to obtain milligrams per liter (mg/l).

*Analysis referred to in text.

APPENDIX G
NATCHITOCHEs PARISH

NOTE.--Three consecutive pages are required for each complete analysis and are indicated thus: G-2, G-2-Continued, and G-2-Continued. Well numbers are repeated on each page.

The following footnotes are used in this Appendix:

¹Sequence number 01 refers to samples collected from USGS wells, 02 refers to samples collected from SCS piezometers located adjacent to USGS wells.

²Divide micrograms per liter (ug/l) by 1,000 to obtain milligrams per liter (mg/l).

*Analysis referred to in text.

APPENDIX H
RAPIDES PARISH

NOTE.--Three consecutive pages are required for each complete analysis and are indicated thus: H-2, H-2-Continued, and H-2-Continued. Well numbers are repeated on each page.

The following footnotes are used in this Appendix:

¹Sequence number 01 refers to samples collected from USGS wells, 02 refers to samples collected from SCS piezometers located adjacent to USGS wells.

²Divide micrograms per liter (ug/l) by 1,000 to obtain milligrams per liter (mg/l).

*Analysis referred to in text.

APPENDIX I
RED RIVER PARISH

NOTE.--Three consecutive pages are required for each complete analysis and are indicated thus: I-2, I-2-Continued, and I-2-Continued. Well numbers are repeated on each page.

The following footnotes are used in this Appendix:

¹Sequence number 01 refers to samples collected from USGS wells, 02 refers to samples collected from SCS piezometers located adjacent to USGS wells.

²Divide micrograms per liter (ug/l) by 1,000 to obtain milligrams per liter (mg/l).

*Analysis referred to in text.

APPENDIX J

WINN PARISH

The following footnotes are used in this Appendix:

¹Sequence number 01 refers to samples collected from USGS wells, 02 refers to samples collected from SCS piezometers located adjacent to USGS wells.

²Divide micrograms per liter (ug/l) by 1,000 to obtain milligrams per liter (mg/l).
