# WATER RESOURCES DATA FOR CALIFORNIA, 1968

## Part 2. Water Quality Records

---

### INTRODUCTION

Water-resources investigations of the U.S. Geological Survey include the collection of water-quality data on the chemical and physical characteristics of surface- and ground-water supplies of the Nation. These data for the 1968 water year for the quality of surface water in California are presented in this report. Data for a few water-quality stations in bordering States are also included. The data were collected by the Water Resources Division of the Geological Survey under the direction of R. Stanley Lord, district chief, Menlo Park, Calif.

Water-quality information is presented for chemical quality, fluvial sediment, and water temperatures. The chemical-quality information includes concentrations of individual dissolved constituents and certain properties or characteristics such as hardness, sodium-adsorption ratio, specific conductance, and pH. Fluvial-sediment information includes suspended-sediment discharges and concentrations and the particle-size distribution of suspended sediment and bed material. Water-temperature data represent once-daily observations except for stations where a continuous record of temperature is obtained. Daily minimums and maximums are reported for the continuous temperature stations.

The Geological Survey has published the annual series of water-supply papers, "Quality of Surface Waters of the United States," from 1941 through 1964 which contained the chemical-quality, temperature, and suspended-sediment data of the water; each volume included data for an area whose boundaries coincided with those of certain natural drainage areas. The series will be continued through the 1965 water year. The records for California are contained in Parts 9-11 of the water-supply-paper series. (See table 3.) These

publications are available in most public libraries. Beginning with the 1964 water year, water-quality records of surface water obtained by the Geological Survey were published in a new series of annual releases on a State-boundary basis. This report, one of that series, is primarily for local and immediate use, and its distribution is limited. These records will be published later in Geological Survey water-supply papers.

Chemical-quality analyses at most stations in this report were analyzed and furnished by the California Department of Water Resources.

Prior to the 1968 water year, data for chemical constituents and concentration of suspended sediment were reported in parts per million (ppm) and water temperatures were reported in degrees Fahrenheit (°F). In October 1967 the Geological Survey began to report data for chemical constituents and concentrations of suspended sediment in milligrams per liter (mg/l) and water temperatures in degrees Celsius (centigrade, °C).

#### COOPERATION

In California the work was done under cooperative agreements with:

California Department of Water Resources  
California Water Quality Control Board  
Bollinas Harbor District  
Monterey County Flood Control and Water Conservation  
District  
Orange County Water District  
San Luis Obispo County Flood Control and Water Conservation  
District  
San Mateo County  
Santa Clara County Flood Control and Water District  
United Water Conservation District  
University of California.

Assistance in the form of funds was given by the Bureau of Reclamation, U.S. Department of the Interior; the Corps of Engineers, U.S. Army; and the Forest Service and the Soil Conservation Service, U.S. Department of Agriculture.

Agencies furnishing assistance were:

Alameda County Water District  
Metropolitan Water District of Southern California  
Kings River Water Association  
Sierra Pacific Power Company.

## DEFINITION OF TERMS AND ABBREVIATIONS

The terms and abbreviations of water-quality and hydrologic data, as used in the text and tabular data of this report, are defined as follows:

Acre-foot (ac-ft) is a quantity of water required to cover 1 acre to a depth of 1 foot and is equal to 43,560 cubic feet or 325,851 gallons. The term is commonly used in measuring volumes of water.

Cfs-day is the volume of water represented by a flow of 1 cubic foot per second for 24 hours. It equals 86,400 cubic feet, 1.983471 acre-feet, or 646,317 gallons. A cfs-day represents a runoff of 0.0372 inch from 1 square mile.

Cubic feet per second (cfs) is a unit expressing rates of discharge. One cubic foot per second is equal to the discharge of a stream of rectangular cross section, 1 foot wide and 1 foot deep, and at an average velocity of 1 foot per second.

Discharge, in its simplest concept, means outflow; therefore, the use of this term is not restricted as to course or location. In this report it represents the total fluids measured in the stream.

Daily mean discharge is the mean discharge for 1 day.

Mean daily discharge is the arithmetic mean discharge for the same day during a specific period of years.

Mean discharge is the arithmetic mean of individual daily mean discharges during a specific period.

Instantaneous discharge (at time of sampling). If the discharge at the time of sampling is reported instead of the daily mean, the heading of the discharge column is "Discharge (cfs)."

Dissolved solids is the residue on evaporation after drying at 180°C for 1 hour. For some water samples, particularly those containing moderately large quantities of soluble salts, the value reported is calculated from the quantities of the various determined constituents using the carbonate equivalent of the reported bicarbonate. The calculated sum of the constituents may be given instead of or in addition to the residue.

Drainage area is that area, in a specified location, measured in a horizontal plane, which is enclosed by a drainage divide.

Drainage basin is a part of the surface of the earth that is occupied by a drainage system, which consists of a surface stream or body of impounded surface water together with all tributary surface streams and bodies of impounded surface water.

Gaging station is a particular site on a stream, canal, lake, or reservoir where systematic observations of gage height or discharge are obtained. When used in connection with a discharge record, the term is applied only to those gaging stations where a continuous record of discharge is obtained.

Hardness of water is the property of water attributable to the presence of alkaline earths and is expressed as equivalent calcium carbonate ( $\text{CaCO}_3$ ). Hardness is a physical-chemical characteristic, not a substance.

Milligrams per liter (mg/l) is a unit for expressing the concentration of chemical constituents in solution. Milligrams per liter represents the weight of the dissolved constituent per unit volume of water. Concentration of suspended sediment expressed in milligrams per liter is based on the weight of sediment in a liter of water-sediment mixture. Sediment concentrations that are expressed in parts per million may be converted to milligrams per liter by using the factors in table 1.

1. Based on water density of 1.000 g/ml and sediment density of 2.65 g/cc.

Partial-record station is a particular site where limited data are collected systematically over a period of years for use in hydrologic analyses.

Particle size is the diameter, in millimeters (mm), of suspended sediment or bed material determined by sieve or sedimentation methods.

Particle-size classification agrees closely with recommendations made by the American Geophysical Union Subcommittee on Sediment Terminology (Lane and others, 1947, p. 937). Their classification is as follows:

Clay:       Smaller than 0.004 mm.  
 Silt:       Between 0.004 and 0.062 mm.  
 → Sand:     Between 0.062 and 2.0 mm.  
 Gravel:    Between 2.0 and 64.0 mm.

The particle-size distributions given in this report do not include organic material, most of which was removed prior to analysis.

Sediment is fragmental material that originates from the disintegration of rocks and is transported by, suspended in, or deposited by, water or air, or is accumulated in beds by other natural agencies (Colby, 1963, p. vi). (See also Langbein and Iseri, 1960, p. 17.) The quantity, characteristics, and cause of the occurrence of sediment in streams are influenced by environmental factors. Some major factors are degree of slope, length of slope, soil characteristics, land usage, and quantity and intensity of precipitation.

Sediment discharge is the rate at which dry weight of sediment passes a section of a stream or is the quantity of sediment, as measured by dry weight or volume, that is discharged in a given time.

Specific conductance is a measure of the ability of a water to conduct an electrical current and is expressed in micromhos per centimeter at 25°C. Because the specific conductance is related to the number and specific chemical types of ions in solution, it can be used for approximating the dissolved-solids content in the water. Commonly, the amount of dissolved solids (in milligrams per liter) is about 65 percent of the specific conductance (in micromhos). This relation is not constant from stream to stream or from well to well and may vary in the same source with changes in the composition of the water.

Sodium-adsorption ratio (SAR) is the expression of relative activity of sodium ions in exchange reaction with soil and is an index of sodium or alkali hazard to the soil. This ratio should be known especially for water used for irrigating farmland.

Streamflow is the discharge that occurs in a natural channel. Although the term "discharge" can be applied to the flow of a canal, the word "streamflow" uniquely describes the discharge in a surface stream course. The term "streamflow" is more general than the term "runoff," which is that part of precipitation that appears in surface streams. Therefore, streamflow may be applied to discharge whether or not it is affected by diversion or regulation.

Suspended sediment is the sediment that at any given time is maintained in suspension by the upward components of turbulent currents or that exists in suspension as a colloid.

Thermograph is a thermometer that continuously and automatically records, on a chart, the water temperature of a stream. "Temperature recorder" is the term used to indicate the location of the thermograph.

Time-weighted average is computed by multiplying the number of days in the sampling period by the concentrations of individual constituents for the corresponding period and dividing the sum of the products by the total number of days. A time-weighted average represents the composition of water that would be contained in a vessel or reservoir that had received equal quantities of water from the stream each day for the water year.

Tons per acre-foot indicates the dry weight of dissolved solids in 1 acre-foot of water. It is computed by multiplying the concentration in milligrams per liter by 0.00136.

Tons per day is the quantity of a substance in solution or suspension that passes a stream section during a 24-hour period.

Total sediment discharge or total sediment load is the sum of the suspended-sediment discharge and the bedload discharge. It is the total quantity of sediment, as measured by dry weight or volume, that is discharged during a given time (Colby and Hembree, 1955).

Water year in Geological Survey reports dealing with surface-water supply is the 12-month period, October 1 through September 30. The water year is designated by the calendar year in which it ends and which includes 9 of the 12 months. Thus, the year ending September 30, 1968, is called the "1968 water year."

Weighted average is used in this report to indicate discharge-weighted average. It is computed by multiplying the discharge for a sampling period by the concentrations of individual constituents for the corresponding period and dividing the sum of the products by the sum of the discharges. A discharge-weighted average approximates the composition of water that would be found in a reservoir containing all the water passing a given location during the water year after thorough mixing in the reservoir.

## DOWNSTREAM ORDER AND STATION NUMBERS

Stations are listed in the same downstream order used in the water-supply papers. Records are listed in a downstream direction along the main stem with all stations on a tributary entering above a main-stem station listed before the station. If a tributary enters between two main-stem stations, it is listed between them. A similar order is followed listing stations on first rank, second rank, and other ranks of tributaries. The indention in the listing of stations in the table of contents of this report indicates the rank of any tributary on which a gaging station or water-quality station is situated and the stream to which it is immediately tributary; each indention represents one rank. This downstream order and system of indention shows which stations are on tributaries between any two stations on a main stem and the rank of the tributary on which each station is situated.

As an added means of identification, each station and partial-record station has been assigned a station number. The numbers have been assigned in the same downstream order used in the annual series of water-supply papers. In assigning station numbers, no distinction is made between partial- and continuous-record stations, so that the number for a partial-record station indicates downstream order position in a list made up of both types of stations. Gaps are left in the numbers to allow for new stations that may be established; hence, the numbers are not consecutive.

The complete 8-digit number for each station, such as 11-3035.00 includes the part number "11" plus a 6-digit number. In this report, the nonessential zeros are not shown. For example, the complete number 11-3035.00 would appear as 11-3035. just to the left of the station name. In this report, the records are listed in downstream order by parts. All records for a drainage basin encompassing more than one State could be arranged in downstream order by assembling pages from the various State reports by station number.

## SPECIAL NETWORKS

Some of the stations for which data are published in this report are included in special networks. These stations are identified by the network title, set in parentheses, under the station name. These networks are as follows:

Hydrologic bench-mark station is one that provides hydrologic data for a basin in which the hydrologic regimes will likely be governed solely by natural conditions. Data collected at a bench-mark station may be used to separate effects of natural from manmade changes in other basins which have been developed and in which the physiography, climate, and geology are similar to those in the undeveloped bench-mark basin.

International Hydrological Decade (IHD) River Stations provide a general index of runoff and materials in the water balance (discharge of water, and dissolved and transported solids) of the world. In the continental United States, IHD River Stations provide indices of runoff and of the general distribution of water in the principal river basins.

Irrigation network stations are water-quality stations located at or near certain streamflow-gaging stations west of the main stem of the Mississippi River. Data collected at these stations are used to evaluate the chemical quality of surface water used for irrigation and the changes resulting from the drainage of irrigated lands. Prior to the 1966 water year, chemical-quality data for irrigation was published in the annual water-supply-paper series, "Quality of Surface Water for Irrigation, Western States."

## COLLECTION AND EXAMINATION OF SAMPLES

Water samples for analysis usually are collected at or near points on streams where gaging stations are maintained for measurement of water discharge. Discharge records for streams in California have been released in the report "Water Resources Data for California, 1968, Part 1. Surface Water Records." Most of these records are used in conjunction with the computations of the chemical constituents and sediment loads in this report.

Data on the quality of surface water were collected daily at some sites and less frequently at other sites. The distribution and number of stations in each river or drainage basin are shown in figure 1.

Dissolved Solids

Data for daily chemical-quality sites include the average chemical characteristics of water for "composite periods" of about a month or less. The methods of collecting and compositing water samples for determination of the kinds and concentrations of material dissolved in water are described by Rainwater and Thatcher (1960). One sample can define adequately the water quality at a given time if the mixture of dissolved material throughout the stream cross section is homogeneous. However, the concentration at different locations in the cross section may vary widely with different rates of water discharge depending on the source of material and the turbulence and mixing of the stream. Some streams must be sampled at several verticals across the channel to determine accurately the load of dissolved solids. The daily chemical-quality data in this report generally represent equal-volume composites for 2- to 31-day periods; the composite periods are selected on the basis of specific conductance of the daily samples and fluctuation of water discharge.

Samples collected at monthly and miscellaneous water-quality stations were analyzed individually.

FIGURE 1.--Drainage-basin boundaries and number and distribution of water-quality stations.

Temperature

Water temperatures were measured at most of the water-quality stations. For daily stations, the water temperatures were taken at about the same time each day in order that the data would not reflect diurnal variations in water temperature. Most large streams have a small diurnal temperature change; small, shallow streams may have a daily range of several degrees and may follow closely the changes in air temperature.

At stations where thermographs are located, the reported record consists of maximum and minimum temperatures for each day and the monthly averages.

To convert temperatures in degrees Fahrenheit to degrees Celsius, subtract 32° and divide by 1.8. The conversions shown by table 2 are to the nearest degree.

### Sediment

At some stations, suspended-sediment samples were collected daily with depth-integrating cable-suspended samplers from a fixed sampling point at one vertical in the cross section. A hand sampler was used at many stations during periods of low flow. Depth-integrated samples were collected periodically at many verticals in the cross section to determine the ratio of the cross-sectional distribution of the concentration of suspended sediment to the daily sampling verticals. During periods of high or rapidly changing flow, samples were taken twice or more often throughout the day at most stations. For periods when no samples were collected, daily loads of suspended sediment were estimated on the basis of water discharge, sediment concentrations observed immediately before and after the periods, and suspended-sediment loads for other periods of similar discharge.

At other stations, suspended-sediment samples were collected periodically with depth-integrating cable-suspended or hand samplers at many verticals in the stream cross section. Although data collected periodically may represent conditions only at the time of observations, such data are useful in establishing seasonal relations between quality and streamflow in predicting long-term sediment-discharge characteristics of the stream.

In addition to the records of the quantities of suspended sediment, records of periodic measurements of the particle-size distribution of the suspended sediment and the bed material are included.

### Turbidity

At some stations in the Russian, Eel, and Mad river basins, samples for the determination of turbidity were collected at the same frequency as samples of suspended sediment. Turbidity, measured in milligrams of silica per liter, is shown in relation to the concentration of suspended sediment of the simultaneously collected sample.

## WATER-SUPPLY PAPERS

Table 3 shows the numbers of the annual series of Geological Survey water-supply papers that give information on quality of surface waters in California. Data for the Colorado River basin are given in part 9, the Great Basin in part 10, and Pacific slope basins in California in part 11.

DIVERSIONS AND RETURN FLOWS AT AND BELOW IMPERIAL DAM

25

9-5255. YUMA MAIN CANAL BELOW COLORADO RIVER SIPHON, AT YUMA, ARIZ.  
(Irrigation network station)

LOCATION (revised).--Lat 32°43'39", long 114°37'13", in NW¼NE¼ sec.35, T.16 S., R.22 E., San Bernardino meridian, Yuma County, at gaging station at Colorado River siphon outlet on Arizona side of river, 0.2 mile upstream from bridge on U.S. Highway 80 over Colorado River at Yuma, 0.3 mile west of old Yuma Territorial Prison, and 3.5 miles downstream from siphon-drop powerplant.

RECORDS AVAILABLE.--Chemical analyses: September 1926 to September 1928, October 1942 to September 1968.

Water temperatures: May 1961 to September 1968.

EXTREMES, 1967-68.--Dissolved solids: Maximum, 1,010 mg/l Jan. 1-3; minimum, 803 mg/l Apr. 1-30.

Hardness: Maximum, 400 mg/l Dec. 1-31; minimum, 352 mg/l Oct. 1-31.

Specific conductance: Maximum daily, 1,680 micromhos Dec. 5; minimum daily, 1,210 micromhos Mar. 1, Apr. 3.

Water temperatures: Maximum, 30°C on several days during July and August; minimum, 8°C Dec. 16, 17, 22.

EXTREMES, 1943-68.--Dissolved solids: Maximum, 1,010 mg/l Jan. 1-3, 1968; minimum, 532 mg/l Jan. 1-10, 1953.

Hardness: Maximum, 520 mg/l July 7, 1962; minimum, 260 mg/l Jan. 1-10, 1953.

Specific conductance: Maximum daily, 1,680 micromhos Dec. 5, 1967; minimum daily, 795 micromhos Jan. 5, 1953.

Water temperatures (1967-68): Maximum, 30°C on several days during July and August 1968; minimum, 8°C Dec. 16, 17, 22, 1967.

## PYRAMID AND WINNEMUCCA LAKES BASIN

10-3459. TRUCKEE RIVER AT FLORISTON, CALIF.  
(Irrigation network station)

LOCATION.--Lat 39°23'40", long 120°01'25", in NW $\frac{1}{4}$ SW $\frac{1}{4}$  sec.30, T.18 N., R.18 E., Nevada County, at bridge at Floriston, 0.2 mile upstream from flume diversion, 2.5 miles upstream from gage at Farad, and 1.8 miles upstream from Farad.

DRAINAGE AREA.--932 sq mi (at gaging station).

RECORDS AVAILABLE.--Chemical analyses: January 1964 to September 1968.

Water temperatures: January 1964 to September 1968.

EXTREMES, 1967-68.--Dissolved solids: Maximum, 70 mg/l Nov. 1-30, Jan. 9-31; minimum, 47 mg/l Oct. 1-31.

Hardness: Maximum, 38 mg/l Dec. 7-13, Jan. 9 to Feb. 19; minimum, 26 mg/l May 1-31.

Specific conductance: Maximum daily, 123 micromhos Feb. 6; minimum daily, 60 micromhos May 28

## PYRAMID AND WINNEMUCCA LAKES BASIN

37

10-3459, TRUCKEE RIVER AT FLORISTON, CALIF.--Continued

## EXTREMES, 1967-68.--Continued

Water temperatures: Maximum, 18°C Aug. 12; minimum, freezing point on several days in December.

EXTREMES, 1964-68.--Dissolved solids: Maximum, 85 mg/l Dec. 1-21, 1964; minimum, 45 mg/l Dec. 22-31, 1964.

Hardness: Maximum, 43 mg/l Mar. 1-31, 1964; minimum, 18 mg/l Dec. 22-31, 1964.

Specific conductance (1964-66, 1967-68): Maximum daily, 141 micromhos Feb. 3, 1964; minimum daily, 39 micromhos Dec. 23, 1964.

Water temperatures: Maximum, 20°C July 24, 1964; minimum, freezing point on several days during winter months.

REMARKS.--Records of daily discharge given for station 10-3460, Truckee River at Farad, Calif.
