Preface

This index of flood maps is part of a catalog of information sources being compiled within the Resource and Land Information Program of the Department of the Interior. It is one of a series of references to studies of importance to resource managers and land use planners.

Index of Flood Maps by U.S. Geological Survey Through 1973

by P. H. Carrigan, Jr.

Abstract

A listing is presented of flood maps prepared by the U.S. Geological Survey through 1973. Maps are listed by State and county and the list provides information on the type of flooding depicted and the reliability of the delineation.

The list was prepared from a computer file, and an available program allows retrieval of data by land-line location, State and county, and Standard Metropolitan Statistical Area (SMSA). The file will be continuously updated.

Introduction

This report provides an index to flood maps prepared by the Geological Survey through 1973, and a description of how maps may be obtained.

The computer file from which the map index was prepared contains three types of data for each map: location, type of information shown in the map, and the reliability of this information.

Map location is given in four ways for the index: State, county, name of standard mapping quadrangle in which flood area lies, and latitude-longitude for southeast corner of quadrangle. If the map covers part of several counties (one or more States), map information in the index is individually listed for each county. The index does not identify Standard Metropolitan Statistical Areas which may be also retrieved from computer file. Flooded streams are not named in the index.

Flood maps present information on the areal extent of inundation by one or more selected floods. The index shows whether the inundated area of the map represents an experienced event of special significance or a theoretical flood having some design importance, such as the 100-year flood.

Reliability of flood boundary delineation varies between maps, depending on availability of data and on the analytical effort in map preparation. Some maps are prepared from data obtained within the flood area, from detailed field surveys, and from complex hydrologic and hydraulic analyses; these maps have the highest degree of reliability. Other maps are prepared quickly from readily available data but without detailed field information; only a reconnaissance level of reliability is provided in these maps. The degree of reliability for each map is indicated in the index.

Inquiries about flood maps for a particular State may be made to:

District Chief
U.S. Geological Survey

at the address listed on pages 4-6.

Map Index File

The land-line location of a mapped flood area is referred to the standard Geological Survey quadrangle (nominally 7-1/2 or 15-minute quad; scales slightly different for Alaska, Puerto Rico, and Virgin Island quads) in which this area lies. The land-line identification includes the mapping scale and latitude and longitude of the southeast corner of the quadrangle, as well as the quadrangle name. If the flood area lies in part of several quadrangles, the name, latitude-longitude, and scale of each quadrangle is listed in the computer file and in the index.

The type of flood information available within the quadrangle area is described in one of three ways: the year in which the mapped area was flooded, 1936, for instance; the frequency at which the delineated area is expected to be flooded, expressed as a recurrent interval in years (100-year, for example); or the symbol 'OCC' indicating a significant flood occasionally (25-50 years) inundates the delineated area.

Three descriptors are used to rate the reliability of each flood map: (1) RECON (reconnaissance) meaning area of inundation was approximately delineated without making field surveys and/or detailed hydraulic and hydrologic analyses; (2) STANDARD meaning delineation of flood area was based on field surveys and detailed hydraulic and hydrologic analyses; and (3) HIGH meaning flood area defined by detailed surveys and analyses supported by observed flood information within or immediately adjacent to reach.

If more than one flood map is available for a quadrangle, then the type of information and reliability of each map is in the index. If more than one flood area was shown in a map sheet (two historic floods, for instance) the type of information and reliability for each area may or may not be listed in the index: if the areas were non-contiguous and for different events all type and reliability information are listed; if the areas superpose over virtually the same reach then only type and reliability for the maximum event are listed.

The political subdivision used to identify the locale of a flood is a county, or its equivalent. For the States of Maryland, Missouri, and Virginia independent cities as well as counties are identified. Equivalent geographical subdivisions for Alaska, Puerto Rico, and Virgin Islands are, respectively, census divisions, municipios, and islands.

The locale of flood area has also been identified in the computer file by the "Standard Metropolitan Statistical Area" (SMSA).

Retrieval System

A computer program, developed by T. A. Wilson, U.S. Geological Survey, provides options for printing indices which list all flood maps available for a State, county, or SMSA; the list may be optionally limited to information pertaining to 7-1/2 or 15-minute quadrangles, as well. Another option will list the flood-map information available for a particular quadrangle.

Inquiries about use of the retrieval system should be directed to Chief Hydrologist, U.S. Geological Survey, National Center, Reston, Va. 22092.

Computer programs have been provided to enter information into the file as new maps become available.
