#### DRAINAGE AREAS FOR ILLINOIS STREAMS

Ву

K. M. Ogata

### ABSTRACT

Drainage areas were tabulated for all streams in Illinois which drain over 100 square miles, at sites where streamflow data have been collected, and at other selected locations. Areas were planimetered on U.S. Geological Survey topographic quadrangle maps and balanced to known areas taken from Smithsonian Geographical Tables of areas of quadrilaterals of the earth's surface (procedures and standards recommended by Subcommittee on Hydrology, Federal Inter-Agency River Basin Committee). Streams are tabulated in sequence; first, the Ohio River basin, followed by the St. Lawrence River basin, and finally, the Mississippi River basin. Streams are listed in downstream order, starting at the headwaters; the rank of the stream system within each basin is indicated by indention. At sites where streamflow data had been collected, previously assigned U.S. Geological Survey eight-digit numbers are used. These numbers, which describe unique sites, increase in downstream order. All locations are identified by reference to a town, land-line location, topographic quadrangle, and county at the point where the drainage area was determined. An alphabetical index is provided.

#### INTRODUCTION

This report lists drainage areas for all streams in Illinois that drain over 100 square miles. It also lists drainage areas for numerous intermediate sites where streamflow data have been collected and for other selected points. It provides uniform, accurately determined drainage area figures for use in hydrologic investigations—such as low-flow frequency, flood frequency, and rainfall—runoff studies. Usually, drainage area is one of the more important parameters required for planning and design of water—related projects.

The drainage area of a stream at a specified location is that area, measured in a horizontal plane, comprising a topographic basin and enclosed by a topographic divide, from which all direct surface runoff drains into it.

Basin divides were delineated on the latest available topographic quadrangle maps, and procedures recommended by the Subcommittee on Hydrology, Federal Inter-Agency River Basin Committee (FIARBC) were used to determine drainage areas shown in this report. In a few instances the delineated basin divides were corrected to reflect man-made changes not shown on the maps, such as effects of municipal storm-sewer systems and diversion of water. The Committee selected the U.S. Geological Survey to coordinate drainage-area data prior to publication. The Survey's district offices in the adjoining States of Iowa, Missouri, Kentucky, Indiana, and Wisconsin furnished data for areas outside Illinois. After computation, copies of the list of drainage areas were forwarded to cooperating Federal, State and local agencies for comments. Where necessary, differences in interpretations of topographic divides were resolved, and the resultant drainage area computations have been coordinated with the several agencies. There are 2,090 sites listed in this report, and maps showing drainage boundaries are available in the files of the Geological Survey office in Champaign.

Drainage areas in this report are stated in the English units of square miles (mi<sup>2</sup>); 1 square mile (mi<sup>2</sup>) equals 2.590 square kilometres (km<sup>2</sup>).

Two maps of the State of Illinois are shown. Figure 1 is a map of the counties to aid in the differentiation of streams with identical names (for example, one Vermilion River flows northwest to the Illinois River basin, another Vermilion River flows southeast to the Wabash River basin; both have headwaters in Ford County). Figure 2 superimposes the major Illinois stream systems over the county outlines.

This report was prepared by the U.S. Geological Survey in cooperation with the Illinois Institute for Environmental Quality.

#### METHOD OF DRAINAGE AREA DETERMINATION

Drainage areas were determined using procedures recommended by the FIARBC, using the latest available topographic quadrangle maps of the U.S. Geological Survey. Maps of two scales were used, either 1:62,500 (1 inch equals 1 mile, approximately) or 1:24,000 (1 inch equals 2,000 feet).

The true areas of the quadrangle maps used were determined from the Smithsonian Geographical Tables on areas of quadrilaterals, then all areas in each quadrangle, whether within or outside the drainage basin being measured, were planimetered and balanced to a tolerance of 0.5 percent. Resultant areas are shown to two significant figures below 1 square mile, to three significant figures between 1 and 1,000 square miles, and to the nearest square mile above 1,000 square miles.

Natural drainage has been redirected in the Chicago-south end of Lake Michigan area of northeastern Illinois and northwestern Indiana. The lower Little Calumet River basin flow has been diverted through the Calumet Sag Channel to the Illinois River basin and is included in the Mississippi River basin drainage area figures (pages 58-61) rather than in those for Lake Michigan (St. Lawrence River basin).

Since January 17, 1900, there has been limited diversion from part of the 22,400 square miles of the Lake Michigan basin into the Illinois River basin through the Chicago Sanitary and Ship Canal, but none of this area is included in the Mississippi River basin drainage area values.

#### EXPLANATION OF DRAINAGE AREA TABLES

U.S. Geological Survey Station Number.--Parts of three major river basins, the Ohio River, the St. Lawrence River, and the Mississippi River, flow through Illinois. U.S. Geological Survey numbers are shown at locations on streams where hydrologic data have been collected. These eight-digit numbers indicate the downstream order of the sites, with the number increasing from the headwaters to the mouth. The first two numbers indicate the major river basin in which the site is located; O3 is the Ohio River basin, O4, the St. Lawrence River basin, and O5, the Upper Mississippi River basin. Flow from the lower Little Calumet River basin originally drained into Lake Michigan, which is in the St. Lawrence River basin. The Little Calumet's prefix O4 has been changed to O5. New numbers have been assigned to indicate the proper downstream order.

<u>Stream and location</u>.--The rank of the stream system is indicated by indention. The Ohio, St. Lawrence, and Mississippi Rivers were considered the first-ranked streams. Each succeeding tributary tabulation is indented two spaces.

Land line location, topographic quadrangle, and county.--These columns are self-explanatory. Infrequently, two quadrangles have the same name; the  $7\frac{1}{2}$ -minute quadrangle was used if available and the 15-minute also may have been used, if necessary to complete an area.

#### Type of site. -- The following abbreviations were used in that column:

- CSG = Crest-stage partial-record station or crest-stage floodprofile station, either active or inactive. Usually, annual maximum stage and discharge values were collected at the active partial-record stations. Discharges are not defined for the flood-profile stations.
- GS = Surface-water gaging station, either active or inactive. Stage or discharge data were collected here, and continue to be if the station is active.
- LPR = Low-flow partial-record station. Discharge measurements were made during periods of base flow. These values may not be the minimum values which occurred during a dry period.
- MQM = Miscellaneous discharge measurement site.
- DA = Drainage area measured at this site for a variety of reasons, none of which fit the above categories.

Drainage area.--Areas are shown to two significant figures below 1 square mile, to three significant figures between 1 and 1,000 square miles, and to the nearest square mile above 1,000 square miles.
