CONVERSION FACTORS

Multiply	By	To obtain
inch (in.)	25.4	millimeter
foot (ft)	0.3048	meter
mile (mi)	1.609	kilometer
acre	0.004047	square kilometer
square mile (mi^2)	2.590	square kilometer
cubic foot per second (ft^3/s)	0.02832	cubic meter per second

Temperature may be converted from degrees Fahrenheit (°F) to degrees Celsius (°C) as follows:

$$°C = 5/9 \times (°F-32)$$

GLOSSARY

Antecedent rainfall.--Rainfall preceding the storm rainfall; the storm rainfall being the main cause of any flooding.

Anticyclone.--Center of high pressure around which winds blow clockwise in the Northern Hemisphere.

Crest.--The highest value of the stage attained by a flood; thus, peak stage, flood crest, or crest.

Convection.--Atmospheric motions, usually in the vertical direction, due to differential temperatures and (or) pressures.

Cubic foot per second (ft^3/s).--The rate of discharge representing a volume of 1 cubic foot of water passing a given point during 1 second.

Cyclone.--Center of low pressure around which winds blow counter-clockwise in the Northern Hemisphere.

Dewpoint.--The temperature to which the air must be cooled (at constant pressure and water vapor content) for saturation to occur.

Discharge.--The volume of water, in cubic feet per second, that passes a given point within a given period of time.

Discharge hydrograph.--A graphical representation of stream discharge at a given point as a function of time.

Drainage area.--That area, measured in a horizontal plane, enclosed by a topographic divide from which direct surface runoff from precipitation normally drains by gravity into a stream above a specified point.

Drainage basin.--Area drained by a given stream and its tributaries.

Flood.--A relatively high flow, as measured either by gage height or discharge, which usually overtops the natural banks along some reaches of a stream.

Flood frequency analysis.--Defines the relation of flood-peak magnitude to probability of exceedance or recurrence interval. Probability of exceedance is the chance that a given flood magnitude will be exceeded in any one year. Recurrence interval is the reciprocal of probability of exceedance and is the average number of years between exceedances. For example, a flood having a probability of exceedance of 0.01 (1 percent) has a recurrence interval of 100 years. Recurrence intervals imply no regularity of occurrence; a 100-year flood might be exceeded in consecutive years or it might not be exceeded in a 100-year period.

Flood peak.--The highest stage or discharge attained by a flood; thus, peak stage or peak discharge.

Flood profile.--A graph of the highest water-surface elevations reached at points along a stream in flood, plotted as distance (as abscissa) against elevation (as ordinate).

Flood stage.--The approximate elevation of the stream when overbank flooding begins.

Front.--The transition zone between two distinct air masses.

Gage height.--The water-surface elevation referred to some arbitrary gage datum.

Jet stream.--High-velocity air currents usually found between 6 and 9 miles above the Earth's surface.

Peak discharge.--See flood peak.

Rainfall-gaging station.--A location where rainfall is measured in a systematic fashion.

Recurrence interval.--See flood-frequency analysis.

Stage.--See gage height.

Stage-discharge rating curve.--A graph showing the relation between the gage height (stage) and the volume of water per unit of time (discharge) flowing in a channel.

Streamflow-gaging station.--A particular site on a stream where systematic observations of gage height and discharge are obtained.

Surface weather.--Weather data collected at or close to ground level.

Water year.--The 12-month period, October 1 through September 30. The water year is designated by the calendar year in which it ends and which includes 9 of the 12 months.

FLOODS OF SEPTEMBER 26-OCTOBER 4, 1986, AND AUGUST 14-17, 1987, IN ILLINOIS

By G.O. Balding and A.L. Ishii

ABSTRACT

During the record-setting floods of September 26-October 4, 1986, and August 14-17, 1987, in Illinois, recurrence intervals of stream discharges exceeded 100 years in some locations. This report includes descriptions of the conditions preceding the storms, the spatial and temporal distributions of rainfall during the storms, and the resulting stage and discharge data for affected streams in Illinois.

The two storm periods differed. The storms of October 2-3, 1986, which triggered the major flooding, were widespread but varied in intensity and duration and were preceded by 2 weeks of nearly continuous rainfall. The storms of August 13-14, 1987, were more localized, more intense, and of shorter duration. Peak discharges of record were recorded at nine stations during the 1986 floods; recurrence intervals of four of the peak discharges exceeded 100 years. Most of the flooding in 1986 was confined to the Illinois River basin. In the 1987 flooding, 11 peak discharges of record were recorded; recurrence intervals of 10 of the peak discharges exceeded 100 years. The flooding in 1987 was confined to the Des Plaines River basin in northeastern Illinois. Antecedent-rainfall data indicate that the antecedent soil moisture exerted a more significant influence in the 1986 flooding than it did in the 1987 flooding.

INTRODUCTION

State and local water-resource planners typically design and evaluate structures with reference to rainfall data from storms that result in floods of 50- to 100-year recurrence intervals. Hydrologic data from such storms, coupled with the available associated climatologic data and a mathematical model, are commonly used to predict drainage-basin response to large storms. A detailed description of the characteristics and responses of large storms is a necessary prerequisite for application of storm data to planning, design, and management of roads, bridges, culverts, and dams. In 1987, the U.S. Geological Survey (USGS), in cooperation with the Illinois Department of Transportation, Division of Water Resources, began a study of the major storms of June 1981 and December 1982 and the corresponding floods (recurrence intervals of 50 to 100 years) (Ishii, 1991). The cooperative effort was later expanded to include the storms and floods of September-October 1986 and August 1987.

Major storms of October 2-3, 1986, and August 13-14, 1987, in Illinois, though of contrasting types, caused record floods and stream discharges with recurrence intervals exceeding 100 years. The storms of October 2-3, 1986, were associated with a cold front that stalled over northern and central Illinois from September 28 through October 3. The storms varied in intensity and duration over a large area. The magnitude of the resulting floods was caused by 2 weeks of nearly continuous rainfall that preceded the October 2-3 storms, as well as the storm rainfall. Antecedent soil moisture exerted a significant influence in the magnitude of the flooding. The storms of August 13-14, 1987, were convective storms of short duration and high intensity over a small area in northeastern Illinois; antecedent rainfall was not an important factor in the resulting floods.

This study effort involved the analysis of data from the National Weather Service precipitation-data network (fig. 1) and the USGS streamflow-gaging-station network in Illinois (figs. 2 and 3).

Purpose and Scope

This report describes the storms and the resulting floods in Illinois during September 17-October 3, 1986, and August 13-14, 1987. The report summarizes antecedent rainfall for the storms, describes the temporal and spatial distributions of rainfall during the storms, and provides hydrologic data and analyses of the resulting floods. Meteorological data presented include synoptic summaries, antecedent-rainfall maps, storm-rainfall maps, and graphs of cumulative rainfall. Hydrologic data and analyses include discharge hydrographs, streamflow data, recurrence intervals, and comparisons of observed peak discharges to previous flood records.

Acknowledgments

The authors gratefully acknowledge the Metropolitan Water Reclamation District of Greater Chicago for furnishing precipitation data.

FLOODS OF SEPTEMBER 26-OCTOBER 4, 1986

During the period September 26-October 4, 1986, intense thunderstorms caused severe flooding in northeastern Illinois and scattered flooding across parts of western, central, and southwestern Illinois (fig. 4). Damage was most severe in Lake and Cook Counties in northeastern Illinois.

Governor James R. Thompson declared the following eight counties as State disaster areas: Lake, Kane, Du Page, and parts of Cook and McHenry Counties, in northeastern Illinois; Tazewell County, in central Illinois; Adams County, in western Illinois; and St. Clair County, in southwestern Illinois. In a letter to the Federal Emergency Management Agency (FEMA), Governor Thompson declared the flood damage to property in northeastern Illinois to be $34.6 million. The flooding caused structural damage to about 1,000 houses, displaced about 15,000 residents, and affected about 260 businesses in the Chicago area. In Tazewell

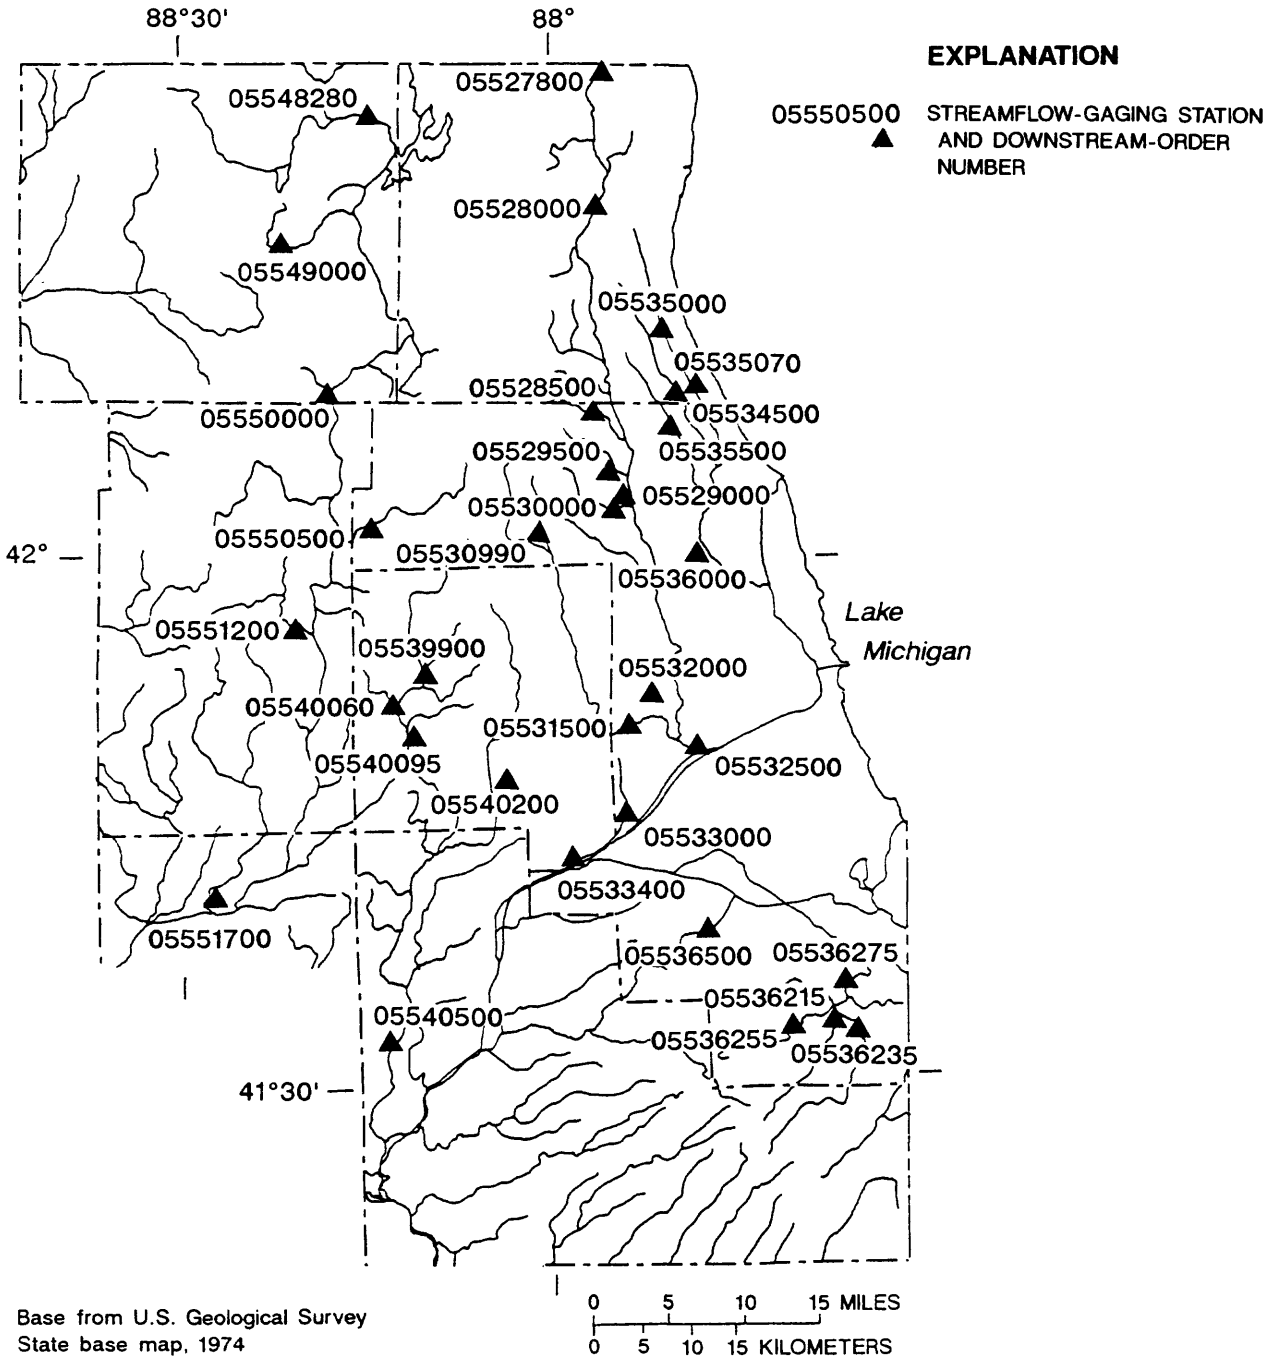

Figure 3.--Location and downstream-order number of streamflow-gaging stations in northeastern Illinois from which data were used.

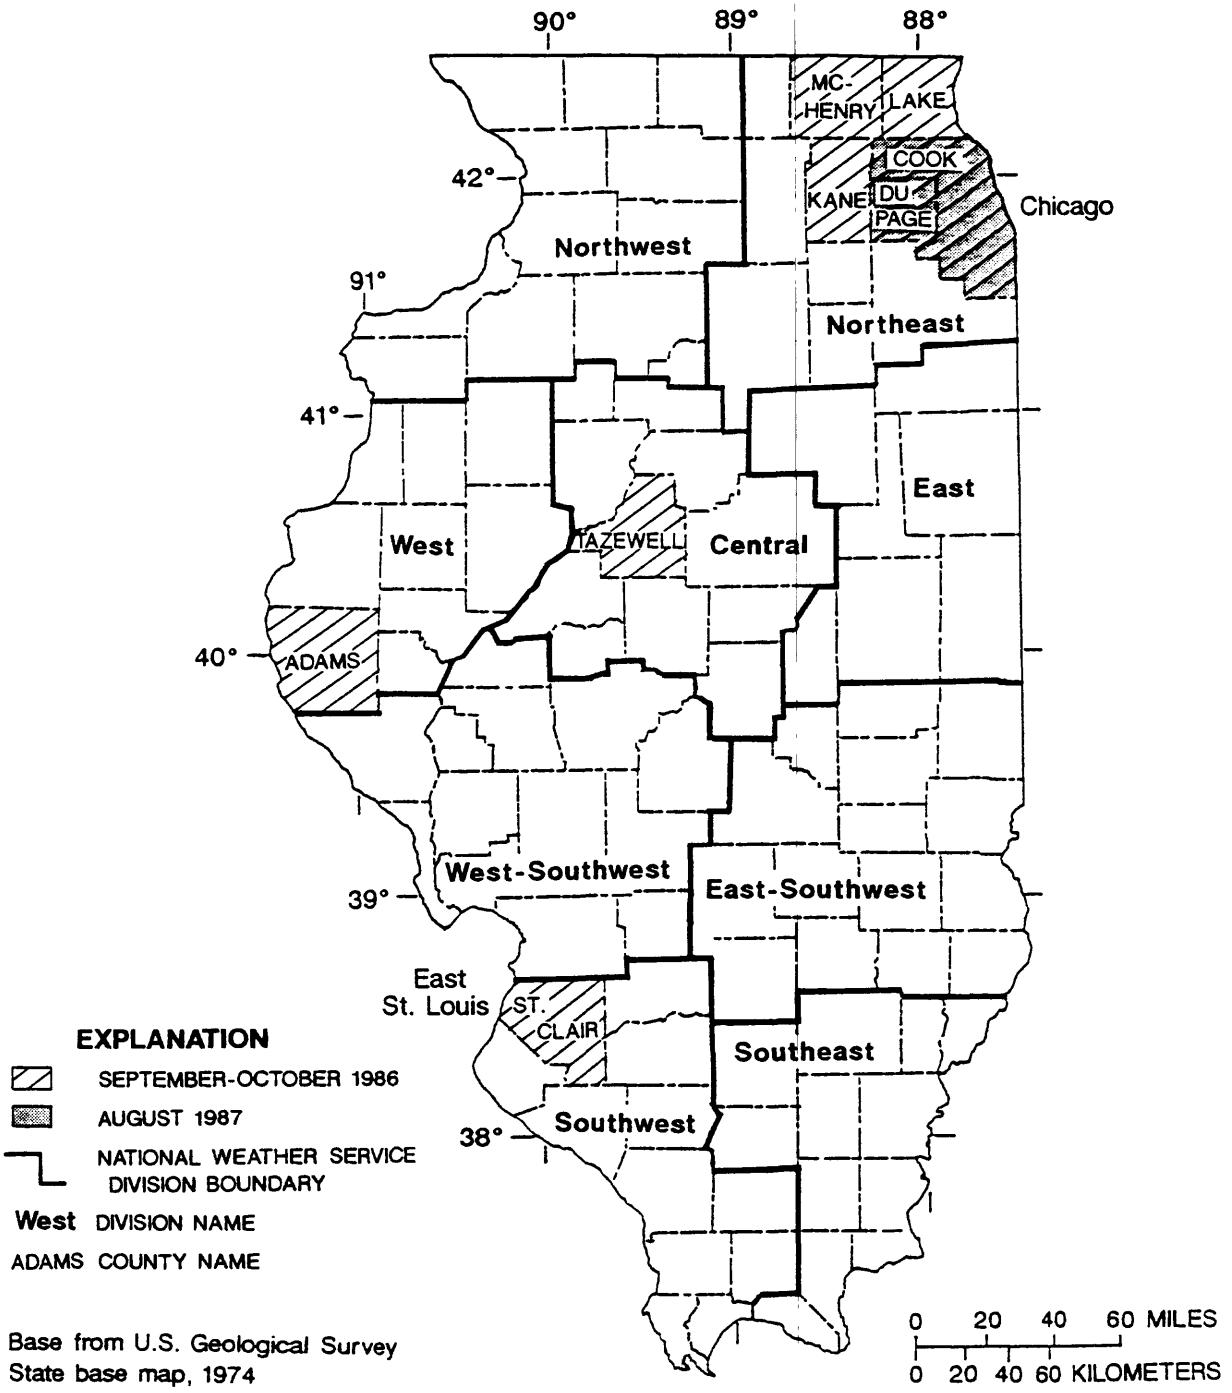

Figure 4.--Counties designated as disaster areas as a result of the floods of September 26-October 4, 1986, and August 14-17, 1987.

County, 10,000 acres of farmland were flooded, whereas in Adams County, 7,000 acres of unharvested crops were submerged. In St. Clair County, 425 people were evacuated from a public-housing project in East St. Louis (Enstad and Karwath, 1986).

On October 7, 1986, the President declared that Illinois had suffered a major disaster because of the severe storms and flooding. Preliminary damage estimates for the State totaled nearly $50 million and included damage to 4,000 homes, more than 600 businesses, and dozens of public structures and facilities (Federal Emergency Management Agency, 1986, p. 3).

Meteorological Setting

During the last half of September and the first few days of October, several cyclonic storm systems developed in the western United States and slowly moved east across Illinois as the polar jet stream advanced southward and retreated. Throughout the period, temperatures in Illinois were higher than normal, with daily highs of about 82°F and lows of about 65°F. Temperatures cooled to about 72 and 62°F for the daily highs and lows, respectively, by October 2 and 3 as a cold front moved in.

On September 15, a cyclone formed in the western United States, as the jet stream was over northern Illinois. The cyclone intensified on September 16 and 17 (fig. 5) and then moved eastward and dissipated on September 18 (fig. 5). The jet stream continued to cut across northern Illinois during September 19-21. The associated stationary front and unstable moist air caused convective rain showers daily in the warm air mass north of the front and the cooler air mass south of the front (fig. 5).

On September 22 and 23, a cyclonic system centered in Canada kept Illinois in a warm-air sector between a warm front to the east and a cold front to the west. Beginning at about 0600 hours central standard time (c.s.t.) September 24, a cyclone centered on Wyoming began to intensify and move northward (fig. 5). By September 25, Illinois was again within the warm air mass between an eastern warm front and a western cold front (fig. 5). As the cyclone moved eastward over Canada, the cold front remained west of Illinois and created the potential for rainfall in Illinois ahead of the front (fig. 5).

On September 26 and 27, another cyclonic storm system developed, and Illinois was again in the central warm-air sector. On September 28, the system became associated with an anticyclone that held the warm-air sector in place until the anticyclone moved eastward and a new cyclonic system developed in Nebraska at about 1800 hours c.s.t. September 28. At about 1700 hours c.s.t. September 29, the western cold front finally entered Illinois, bringing heavy rains. The cold front moved south to central Illinois and remained there until October 4. Illinois had thus been in the warm-air sector between two fronts during September 22-29. Warm, moist, low-level winds from the Gulf of Mexico provided the moisture for the heavy precipitation (Dietrich, 1989, p. 5). The final heavy rain showers associated with the cold front on October 2 and 3 (fig. 5) added to already saturated ground and swollen rivers.

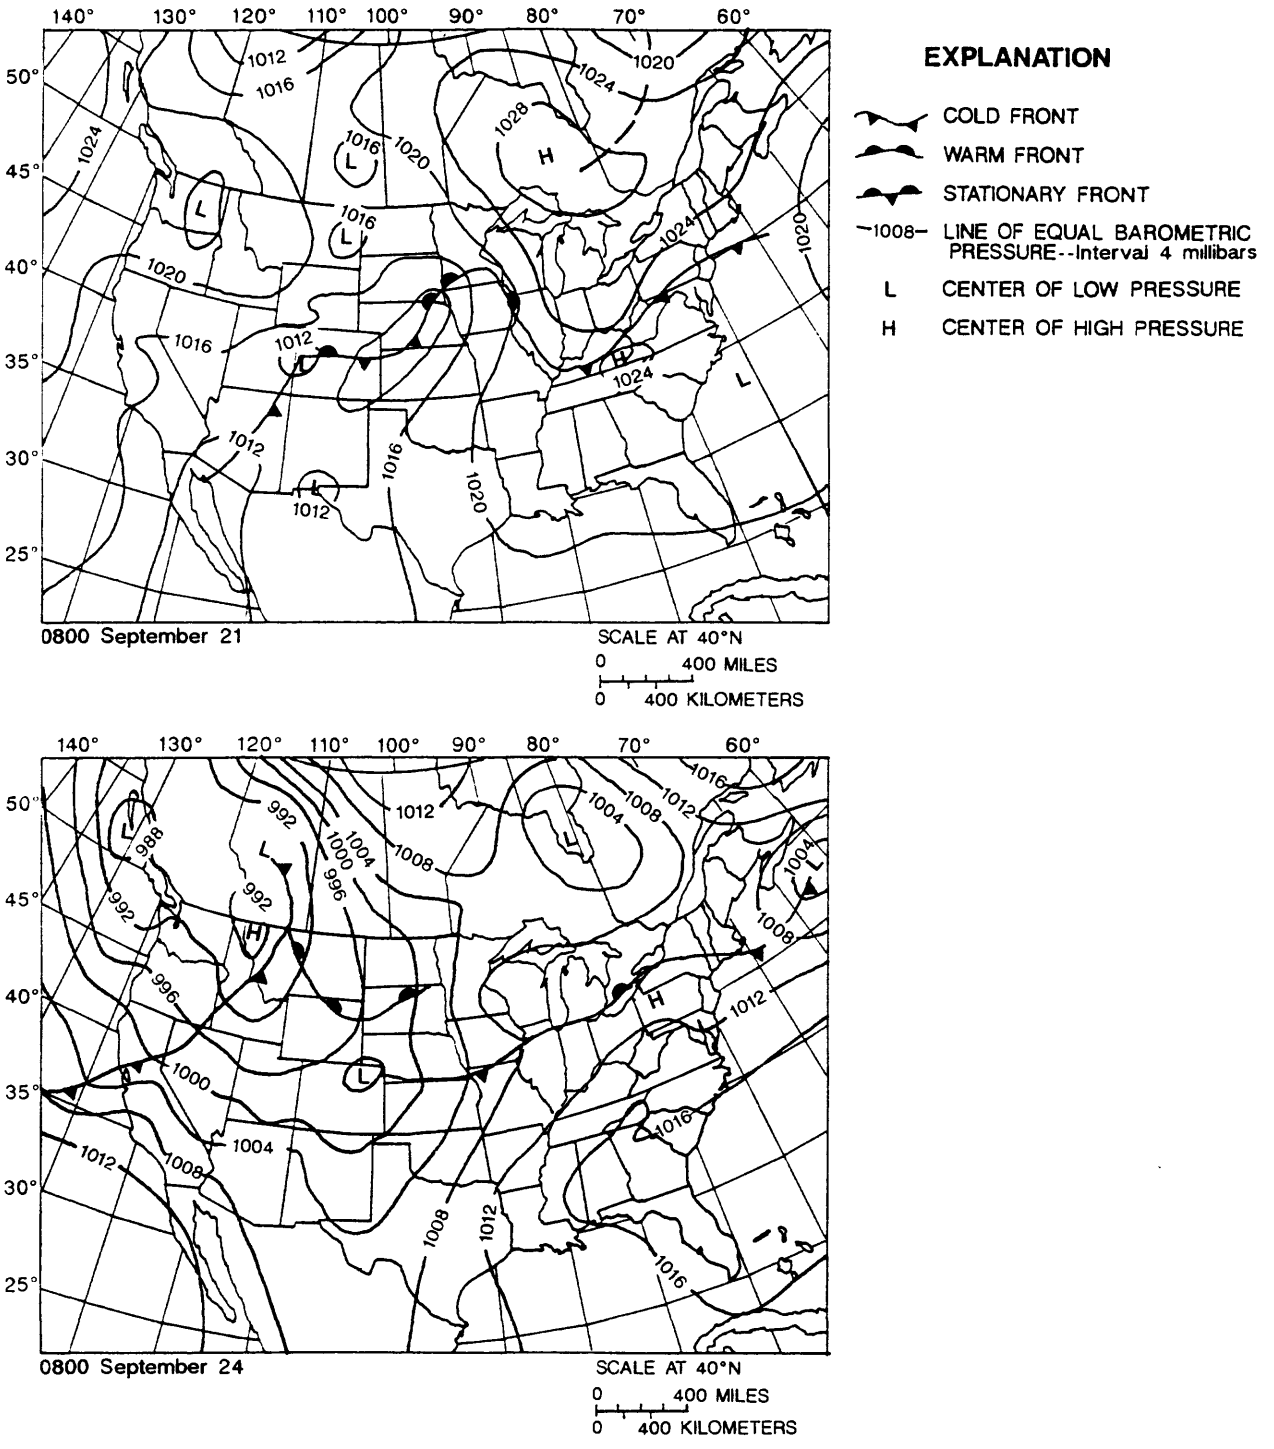

Figure 5.--Surface weather over the United States at 0800 hours central standard time on September 17, 18, 21, 24, 25, 30, and October 3, 1986--Continued. (Data from the National Weather Service, 1986a-c.)

Characteristics of Rainfall Distribution

Rainfall across the middle of the State during September was 184 percent of normal in eastern Illinois, 220 percent of normal in central Illinois, and 216 percent of normal in western Illinois. The northern part of the State was the hardest hit; rainfall was 251 percent of normal in the northeast and 235 percent of normal in the northwest (R.G. Semonin, Illinois State Water Survey, written commun., 1986).

During September 18-20, when the first warm air mass was stalled over central Illinois, accumulated rainfall in northeastern Illinois amounted to 0.10 in. or less around Antioch (5)[1] and Waukegan (170) to almost 1.5 in. at Chicago O'Hare International Airport (32) and more than 2.1 in. at Joliet Brandon Road Dam (82). Rainfall elsewhere in the State ranged from about 0.5 to more than 4.0 in. in the northwestern part, about 0.7 to more than 4.2 in. in the western part, and about 2.0 to almost 7.2 in. in the central part. During September 25-27, accumulated rainfall across northern Illinois amounted to 4.18 in. at Freeport (55), 5.39 in. at Antioch (5), 5.43 in. at Marengo (95), 7.70 in. at Waukegan (170), and 3.62 in. at Wheaton (173).

Total antecedent rainfall for the respective 10- and 5-day periods preceding the storms of October 2-4 are shown in figure 6. Antecedent rainfall may help indicate the ability of the soils to receive additional rainfall as infiltration. Long-term antecedent rainfall aids in the assessment of streamflows. As much as 3.46 in. of rain fell in the northwestern part of the State during the 5-day period September 28-October 2. Elsewhere in the State, as much as 3.91 in. of rain fell in the northeastern part, 4.15 in. fell in the western part, 2.29 in. fell in the central part, 5.65 in. fell in the eastern part, and 4.47 in. fell in the west-southwestern part.

The temporal and spatial distributions of the storm rainfall indicate that the first showers occurred in the western and central parts of the State during September 19-20 as a result of the stationary front over central Illinois. These intense storms were of short duration; but, as the front moved northward, the duration and intensity of the storms increased (figs. 7 and 8). The rainfall recurrence intervals (RI's) for the 10- and 3-day storm periods of September 25-October 4 and October 2-4, for rainfall at selected rainfall-gaging stations, are listed in table 1 (at back of report). A comparison of the two periods shows that the RI's for the 10-day storm period were much higher than those for the 3-day storm period, indicating that the 10-day storm period played a major part in the flooding that took place in October.

The spatial distribution of the 3-day total storm rainfall is shown on plate 1A (in pocket). The heaviest rains were in and near Avon (8) in western Illinois; Chenoa (29), Lacon (88), and Mackinaw (93) in central Illinois; and Fairbury (51) in eastern Illinois (fig. 1).

[1]Numbers in parentheses correspond to location numbers in figure 1.

Description and Analysis of Floods

Major flooding took place in the Des Plaines River basin. The heavy rains resulted in peak discharges of record on the Des Plaines River, Skokie River, and St. Joseph Creek. In the Fox River basin, peak discharges of record were recorded on Nippersink Creek and Boone Creek. In the Vermilion River basin, a peak discharge of record was reached on the North Fork Vermilion River. High discharges were recorded at other streams--Kickapoo Creek, Mackinaw River, Spoon River, Evelyn Branch, Drowning Fork, and La Moine River--but these discharges were not peak discharges of record. The previously recorded maximum peak stages and discharges, and the peak stages and discharges determined at streamflow-gaging stations during the flooding of late September and early October, are listed in table 2 (at back of report). The RI's of the floods were determined by methods recommended by the Interagency Advisory Committee on Water Data, Hydrology Subcommittee (1982) and regional relations described by Curtis (1987). The RI's of the floods also are listed in table 2, and their spatial distribution is shown in figures 9 and 10. Streamflow hydrographs for selected sites in the Illinois River basin where RI's were 15 years or more are shown in figure 11. A comparison of the rainfall RI's (listed in table 1) with the flood RI's (listed in table 2) indicates that the severity of the flooding is reflected more in the RI's of 10-day rainfall than in the RI's of 3-day rainfall. The RI's of the 3-day rainfall were much smaller than the RI's of the flood.

Ohio River Basin

No peak discharges of record were recorded for Illinois streams tributary to the Ohio River. Streamflow in the eastern and southeastern parts of the State reflected the small amount of rainfall there; RI's of peak discharges were less than 2 years.

Upper Mississippi River Basin Above The Illinois River

No peak discharges of record were recorded for Illinois streams tributary to the upper Mississippi River above the Illinois River. Most of the peak discharges resulting from the storms of late September to early October had RI's of 5 years or less. Exceptions were the Sinsinawa River near Menominee (05414820), on September 29, where the peak discharge of 6,660 ft^3/s had an RI of 7 years, and Bear Creek near Marcelline (05495500), on October 3, where the peak discharge of 20,700 ft^3/s had an RI of 15 years. On the main stem of the Mississippi River, the peak discharge of 201,000 ft^3/s at Clinton, Iowa (05420500), on October 6, had an RI of 10 years, whereas the peak discharge of 268,000 ft^3/s at Keokuk, Iowa (05474500), on October 6, had an RI of 20 years.

Illinois River Basin

In the Kankakee River basin, no peak discharges of record were recorded. The only annual peak discharge that was recorded during the flood period was on the Kankakee River at Momence (05520500); the RI was less than 2 years.

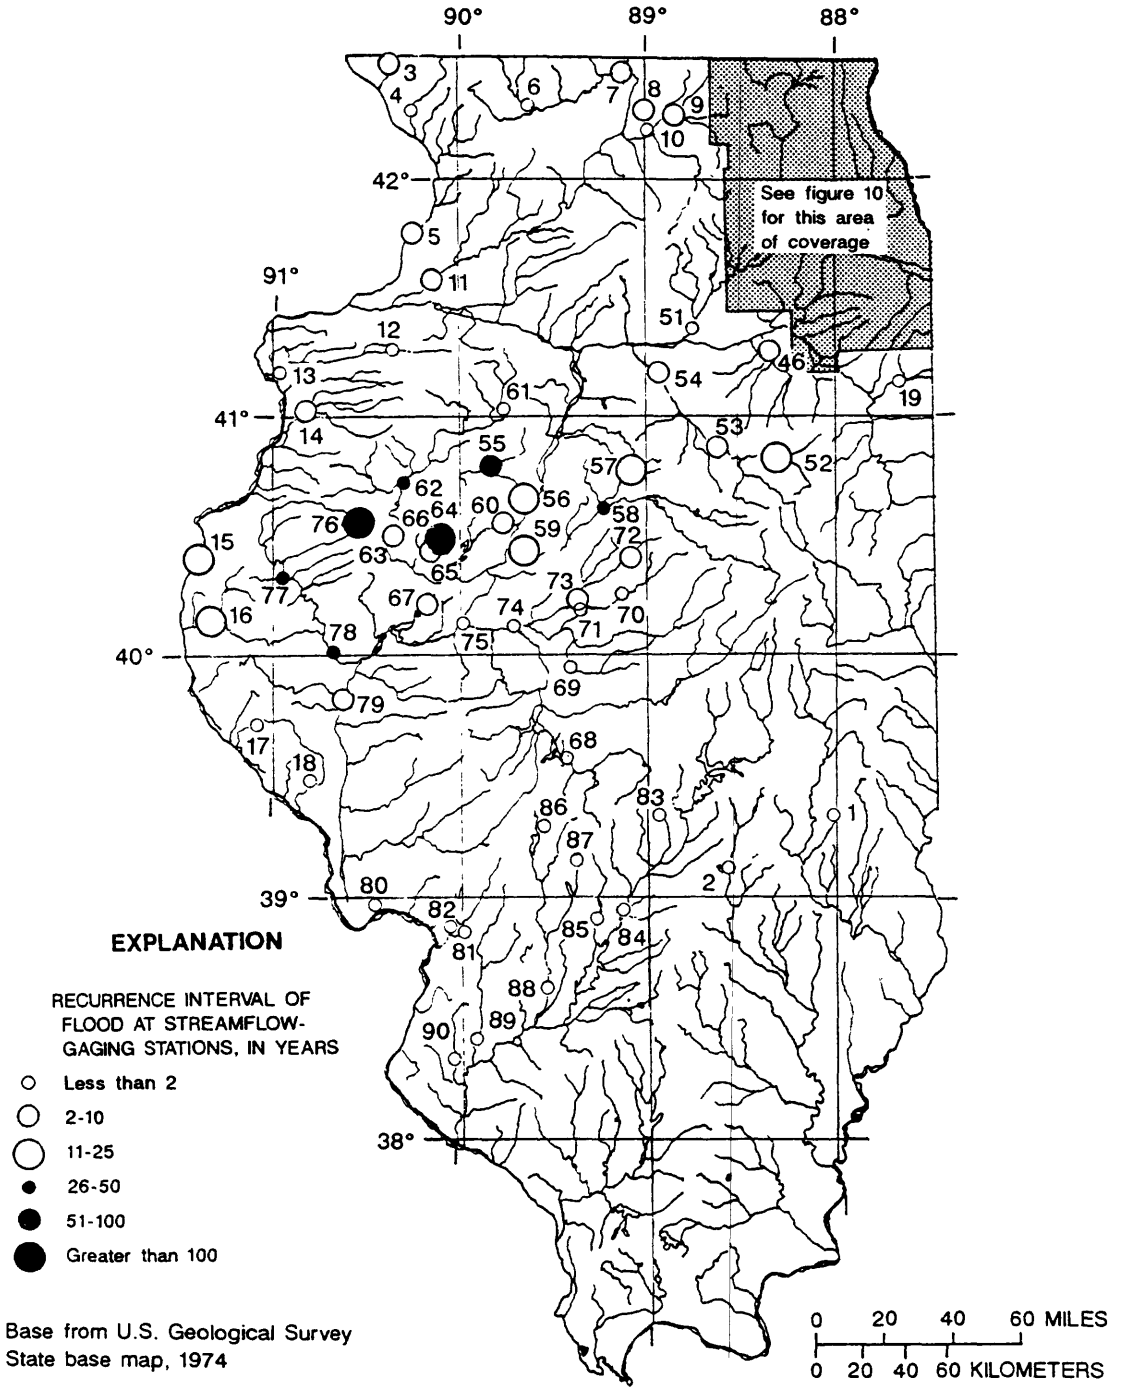

Figure 9.--Recurrence intervals for the floods of late September and early October 1986 at selected streamflow-gaging stations in Illinois (numbers are referenced to table 2).

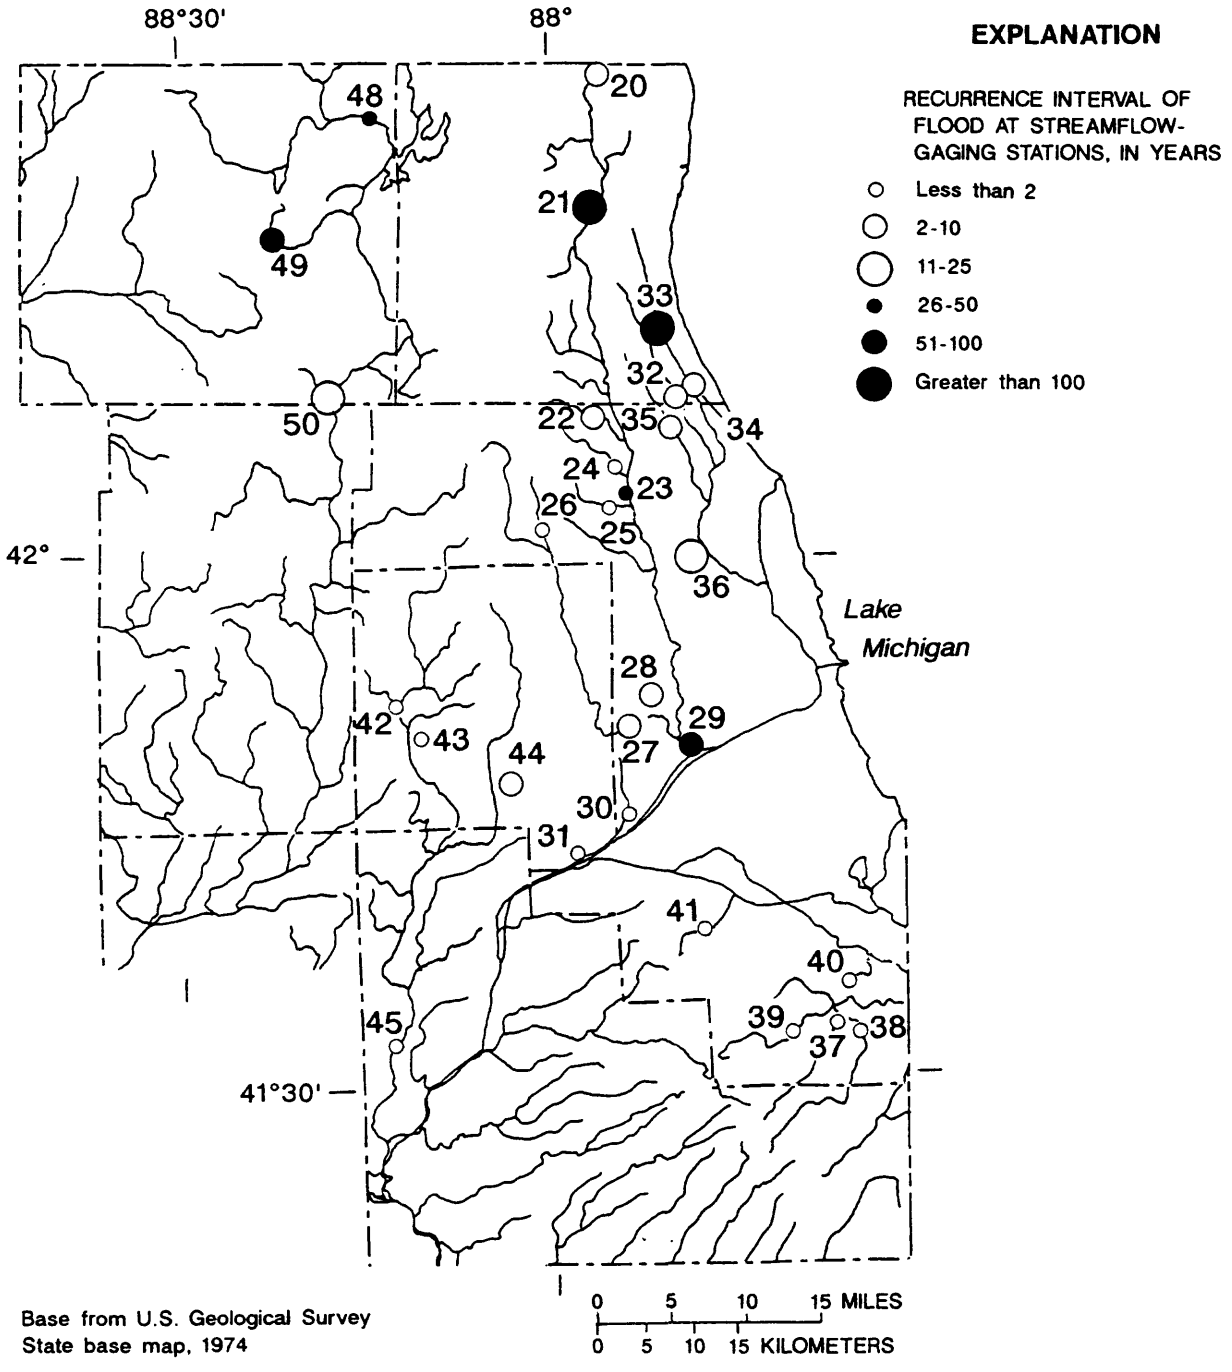

Figure 10.--Recurrence intervals for the floods of late September and early October 1986 at selected streamflow-gaging stations in northeastern Illinois (numbers are referenced to table 2).

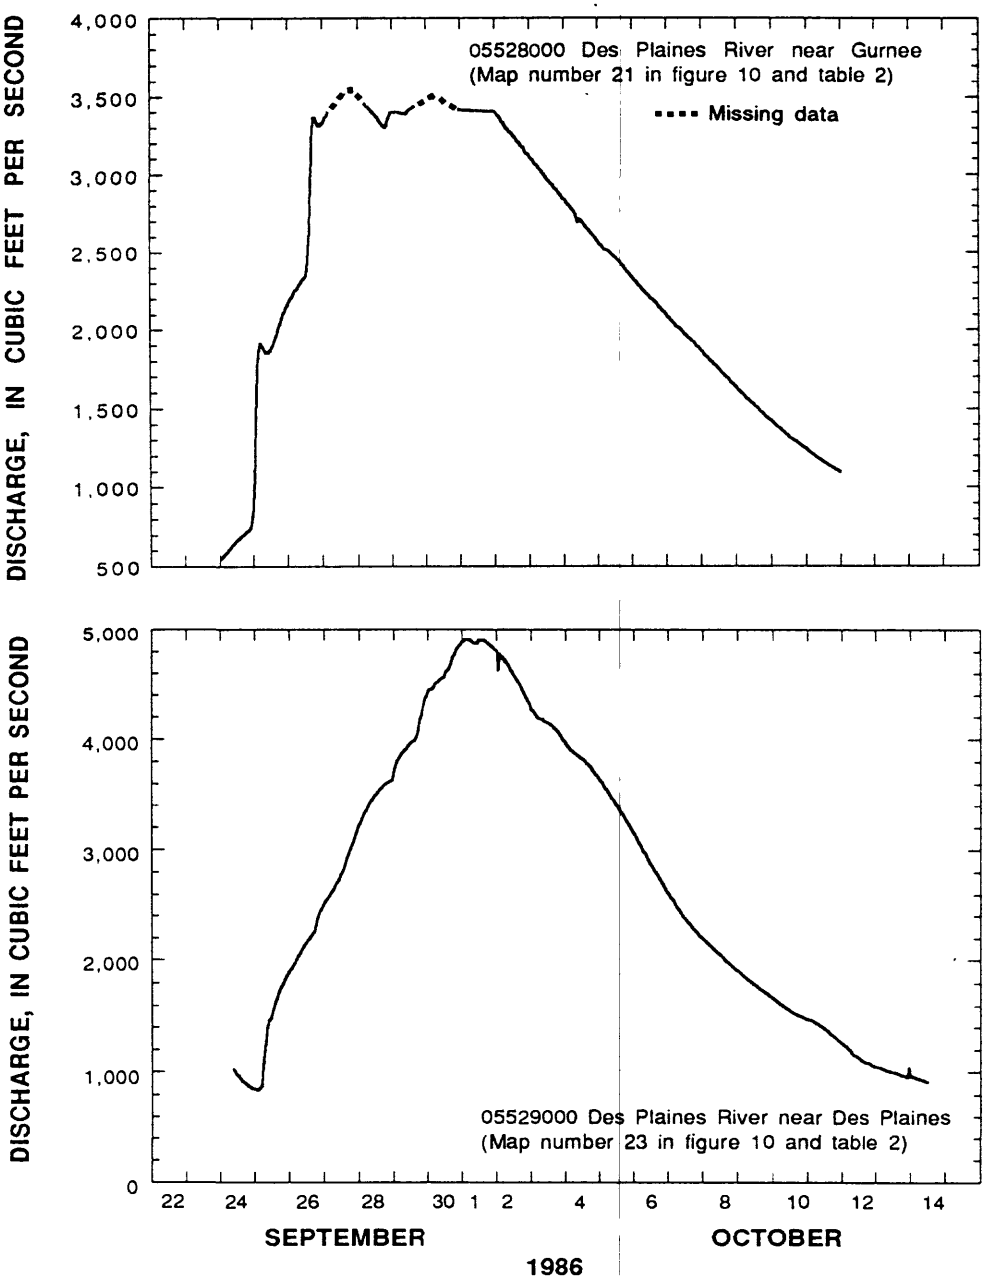

Figure 11.--Streamflow for selected streams in the Illinois River basin, September-October 1986.

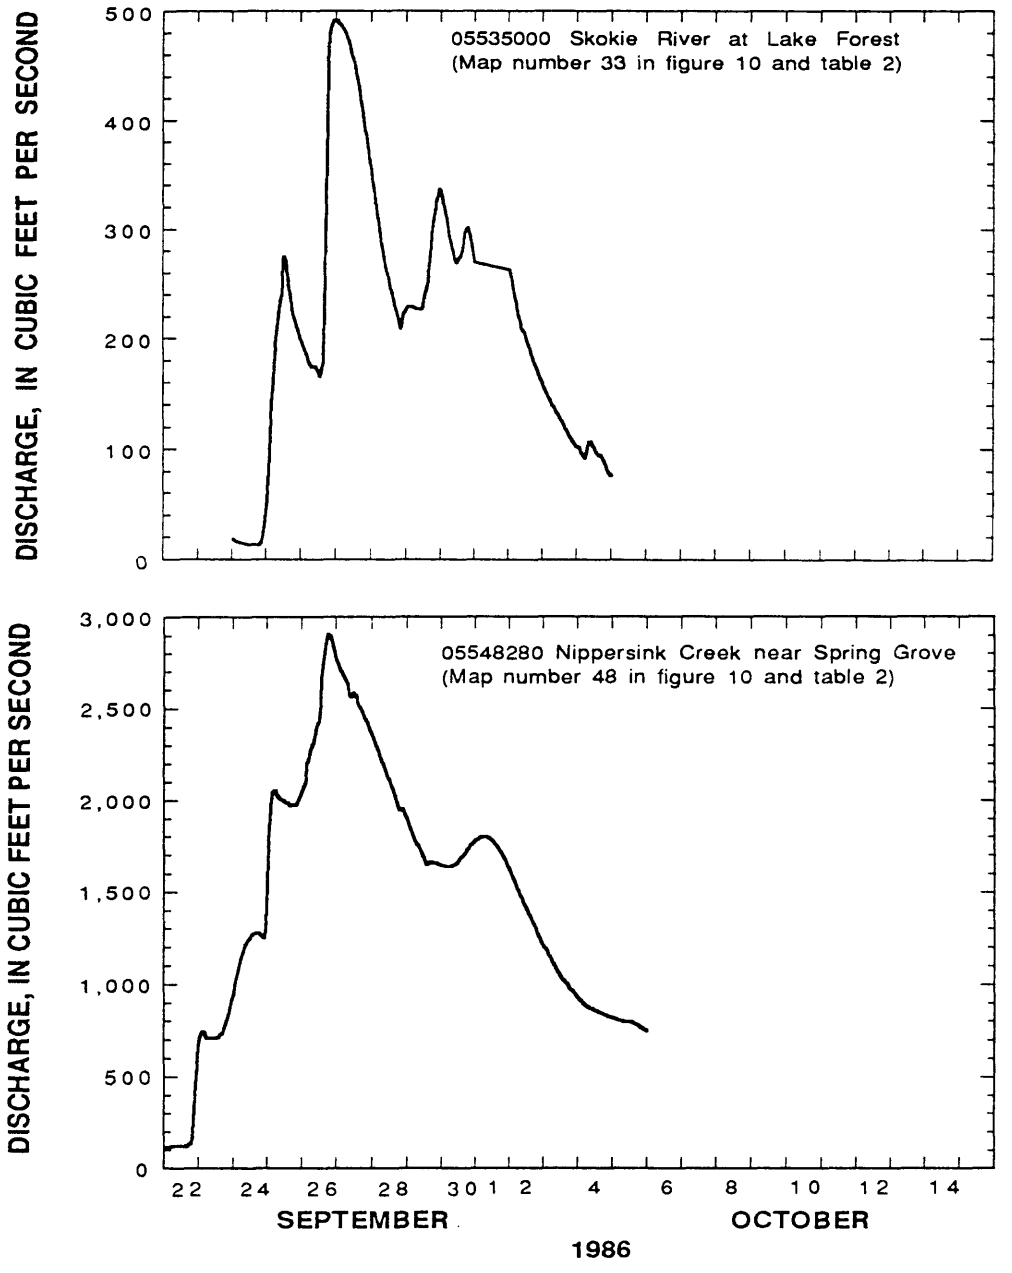

Figure 11.--Streamflow for selected streams in the Illinois River basin, September-October 1986--Continued.

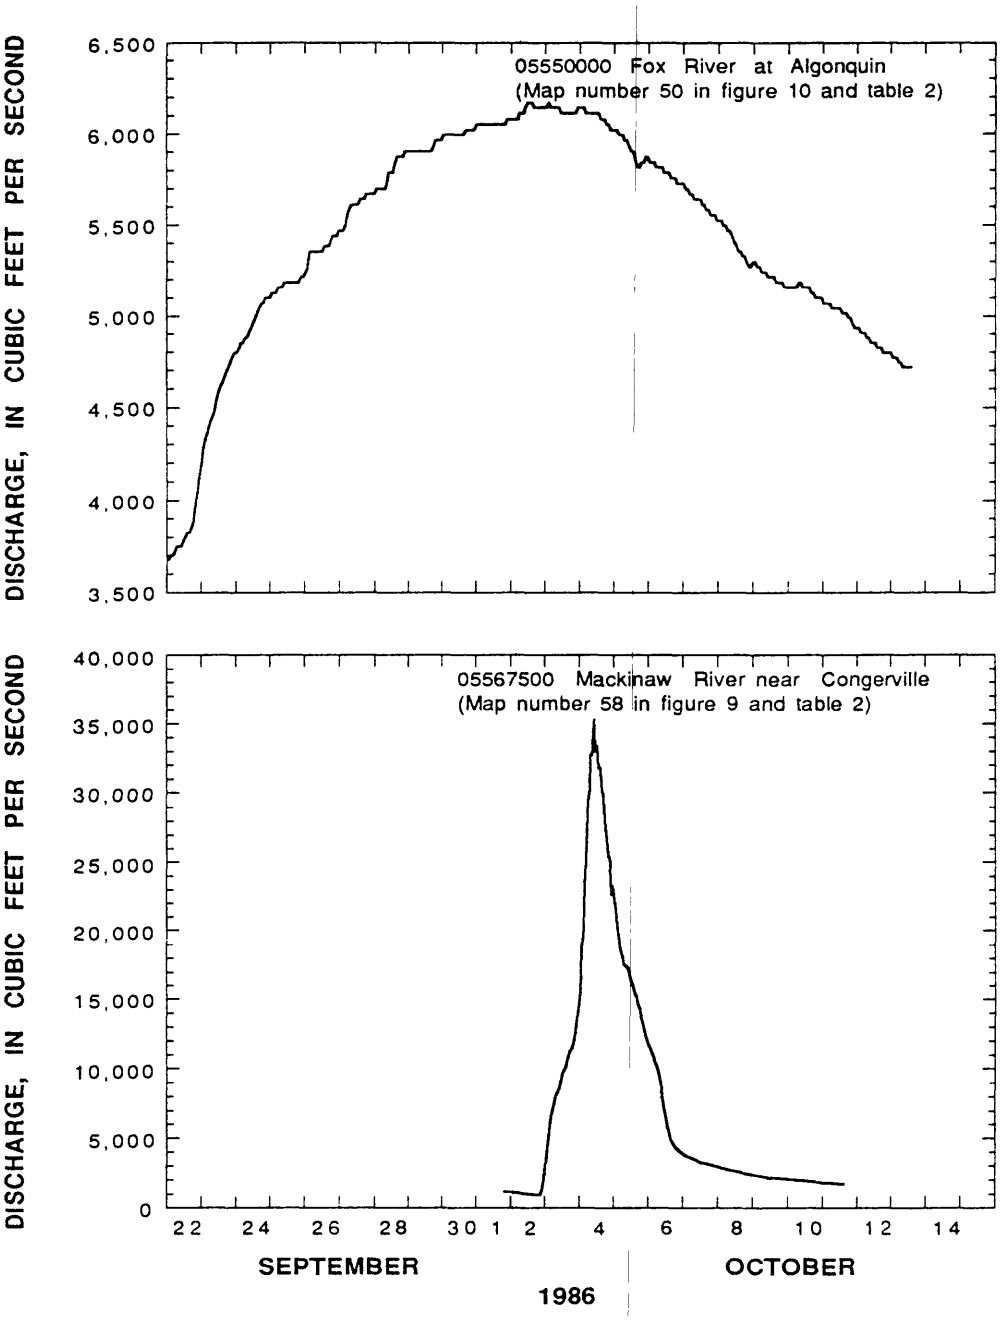

Figure 11.--Streamflow for selected streams in the Illinois River basin, September-October 1986--Continued.

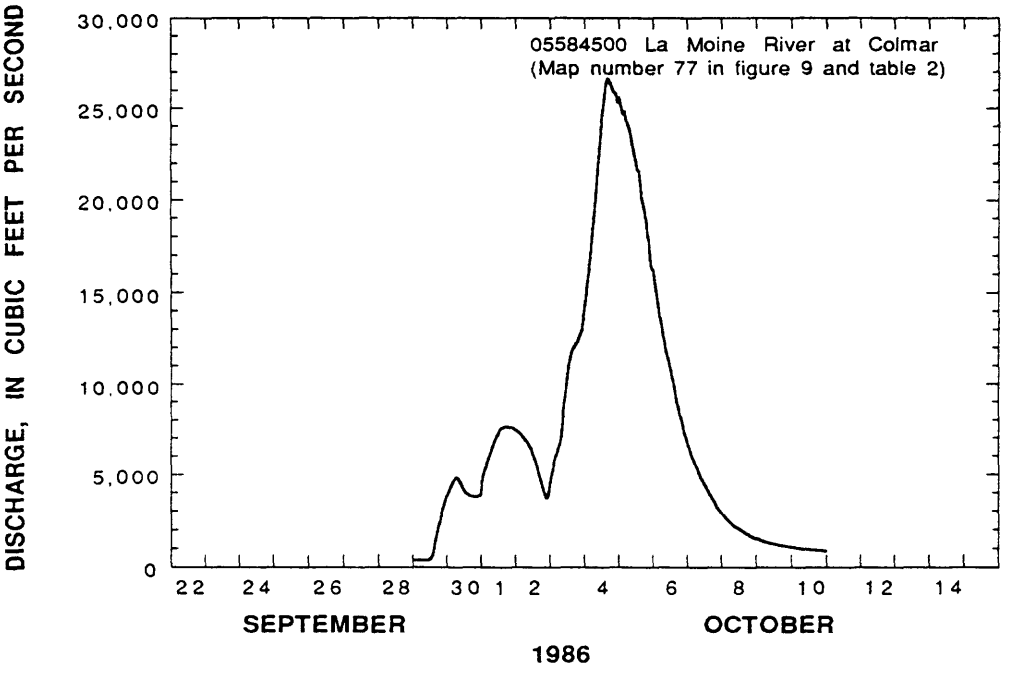

Figure 11.--Streamflow for selected streams in the Illinois River basin, September-October 1986--Continued.

The streamflow-gaging station that is the farthest upstream on the Des Plaines River in Illinois is at Russell (05527800), where the peak discharge of 1,640 ft^3/s, on September 27, corresponds to an RI of 9 years. The maximum discharge for 41 years of record, 3,530 ft^3/s at a stage of 11.95 ft, occurred on September 27 on the Des Plaines River near Gurnee (05528000); the RI was greater than 100 years. The discharge near Gurnee exceeded the previous maximum of April 1960 by 460 ft^3/s; stage was 1.31 ft higher. Downstream, a discharge of 4,900 ft^3/s was recorded on the Des Plaines River near Des Plaines (05529000) on October 1. This peak discharge of record corresponds to a 50-year RI and exceeds the previous maximum of 46 years of record by 230 ft^3/s; stage of the previous maximum peak discharge was exceeded by 2.32 ft. The Des Plaines River at Riverside (05532500) peaked on October 3 at a discharge of 7,590 ft^3/s and a stage of 8.87 ft. The peak at Riverside corresponded to an RI of 70 years and exceeded the maximum peak discharge for 43 years of record by 1,080 ft^3/s and the corresponding stage by 0.59 ft. The maximum discharge (492 ft^3/s at a stage of 8.27 ft) for 35 years of record for Skokie River at Lake Forest (05535000) occurred on September 26, had an RI exceeding 100 years, and surpassed the previous peak discharge of July 1982 by 57 ft^3/s but at a stage 0.08 ft lower. At the next streamflow-gaging station downstream, Skokie River near Highland Park (05535070), the peak discharge recorded on September 30 had an RI of 9 years. At the North Branch Chicago River at Niles (05536000), the peak discharge of 1,800 ft^3/s on September 29 corresponded to an RI of 20 years. Station data for

Des Plaines River near Gurnee (05528000), Des Plaines River near Des Plaines (05529000), and Skokie River at Lake Forest (05535000) are listed in table 3 (at back of report). (Times shown in table 3 are central daylight time rather than central standard time, which is used elsewhere in this report).

In the Fox River basin, peak discharges of record were recorded on two tributaries to the Fox River. At Nippersink Creek near Spring Grove (05548280 with 21 years of record), the discharge of 2,910 ft^3/s recorded on September 26 exceeded the previous maximum by 480 ft^3/s, and the corresponding stage was exceeded by 1.23 ft; the RI was 35 years. At Boone Creek near McHenry (05549000, 39 years of record), the discharge of 345 ft^3/s (on September 27) exceeded the previous maximum by 69 ft^3/s, and the corresponding stage was exceeded by 0.50 ft; the RI was 60 years. Flow from these two tributaries contributed to the peak flood discharge of 6,170 ft^3/s on October 3 for the Fox River at Algonquin (05550000), which had an RI of 25 years. Downstream, the Fox River at its mouth at Dayton (05552500) peaked on October 4 at 10,700 ft^3/s, corresponding to an RI of less than 2 years. Station data for Nippersink Creek near Spring Grove (05548280) and Fox River at Algonquin (05550000) are listed in table 3.

In the Vermilion River basin, a peak discharge of record was recorded on October 3 at North Fork Vermilion River near Charlotte (05554000, 44 years of record). The record discharge of 4,900 ft^3/s (RI of 20 years) exceeded the previous maximum of May 1970 by 350 ft^3/s, and the corresponding stage was exceeded by 0.96 ft. Downstream, the Vermilion River at Pontiac (05554500) and near Leonore (05555300) peaked on October 4 and 5; RI's of peak discharges were 5 and 7 years, respectively.

In the Kickapoo Creek basin, Kickapoo Creek near Kickapoo (05563000, 42 years of record) crested at a record stage of 18.85 ft on October 3, exceeding the previous record set in July 1967 by 1.77 ft. The record stage exceeded the existing stage-discharge rating curve, but it was estimated to be equivalent to a discharge exceeding 30,000 ft^3/s and equal to or greater than a 50-year RI. Downstream, Kickapoo Creek at Peoria (05563500) peaked at 19,700 ft^3/s; the RI was 15 years.

In the Mackinaw River basin, no peak discharges of record were recorded, but the peak discharge at Panther Creek near El Paso (05567000) on October 3 corresponded to a 15-year RI. At the Mackinaw River near Congerville (05567500), the recorded discharge of 35,300 ft^3/s on October 4 corresponded to a 50-year RI. Downstream, the Mackinaw River near Green Valley (05568000) peaked at a discharge of 23,400 ft^3/s, also on October 4, which corresponded to a 15-year RI. Levee breaks were reported to have occurred on October 4 (Graff, 1986), which, in part, may account for the 10,000 acres of farmland flooded in Tazewell County, and for the peak discharge near Green Valley being less than that upstream near Congerville. Station data for Mackinaw River near Congerville (05567500) are listed in table 3.

In the Spoon River basin, no peak discharges of record were recorded, but Spoon River at London Mills (05569500) peaked on October 4 at 26,400 ft^3/s, a discharge that corresponded to a 30-year RI. Downstream at Seville (05570000), the peak was recorded on October 5 at 21,400 ft^3/s (RI of 7 years). On October 3, at Evelyn Branch near Bryant (05570360) the discharge of 276 ft^3/s

exceeded the 100-year RI but did not exceed the discharge of record of 325 ft^3/s established the previous June. Other peak discharges recorded in the basin during the flood had RI's of 3 years or less.

In the Sangamon River basin, peak discharges generally were less than the annual flood (RI less than 2 years). At Sugar Creek near Bloomington (05580950) and near Hartsburg (05581500), however, peaks corresponded to RI's of 4 and 8 years, respectively.

No peak discharge of record was recorded at any stream site in the La Moine River basin, but some flood peaks of note did occur. At Drowning Fork at Bushnell (05584400), a peak stage of 14.07 ft exceeded the previous maximum of 12.92 ft (3,500 ft^3/s) and was off the stage-discharge rating curve. It was estimated that the peak discharge at Bushnell exceeded the 100-year RI. Peak discharges of 28,700 ft^3/s at the La Moine River at Colmar (05584500) and 23,400 ft^3/s at Ripley (05585000) corresponded to RI's of 30 and 35 years, respectively. Station data for La Moine River at Colmar (05584500) are listed in table 3.

Upper Mississippi River Basin Below The Illinois River

The Mississippi River at Grafton (05587450) peaked at 423,000 ft^3/s on October 10; the corresponding RI was less than 2 years. Streams in the Cahokia Creek and Kaskaskia River basins peaked between September 30 and October 7, and these discharges also had RI's of less than 2 years.

FLOODS OF AUGUST 14-17, 1987

During August 13-14, 1987, intense thunderstorms caused severe flooding in northeastern Illinois and minor flooding in northwestern Illinois. Damage was most severe in the communities along the Des Plaines River and Salt Creek. In Cook County, about 8,900 buildings were affected by flooding or sewer backup; in Du Page County, about 7,500 buildings were affected. The total number of single-family units affected was about 11,500. Private-property damage was estimated at $53 million, and public-property damage was estimated at $9.4 million (Curtis, 1990, p. 50). The flooding claimed three lives in the Chicago area and a fourth near Rockford (National Oceanic and Atmospheric Administration, 1987a, p. 27). On August 14, Governor James R. Thompson declared Cook and Du Page Counties State disaster areas (fig. 4). The counties were declared Federal disaster areas on August 21, 1987 (Federal Emergency Management Agency, 1987, p. 3). The effect of flooding on transportation to and from Chicago O'Hare International Airport is shown in figure 12.

Meteorological Setting

On the evening of August 13, 1987, a stationary front was located across northern Missouri and Illinois through central-eastern Michigan. The surface analysis for 2100 hours c.s.t. on August 13 shows that all of Illinois, except the extreme northwest, was in the warm air mass southeast of the front (fig. 13).

Figure 12.--Vehicles on the Kennedy Expressway and a southbound Chicago Transit Authority train stranded at the Addison Street overpass between downtown Chicago and Chicago O'Hare International Airport, August 14, 1987. ()

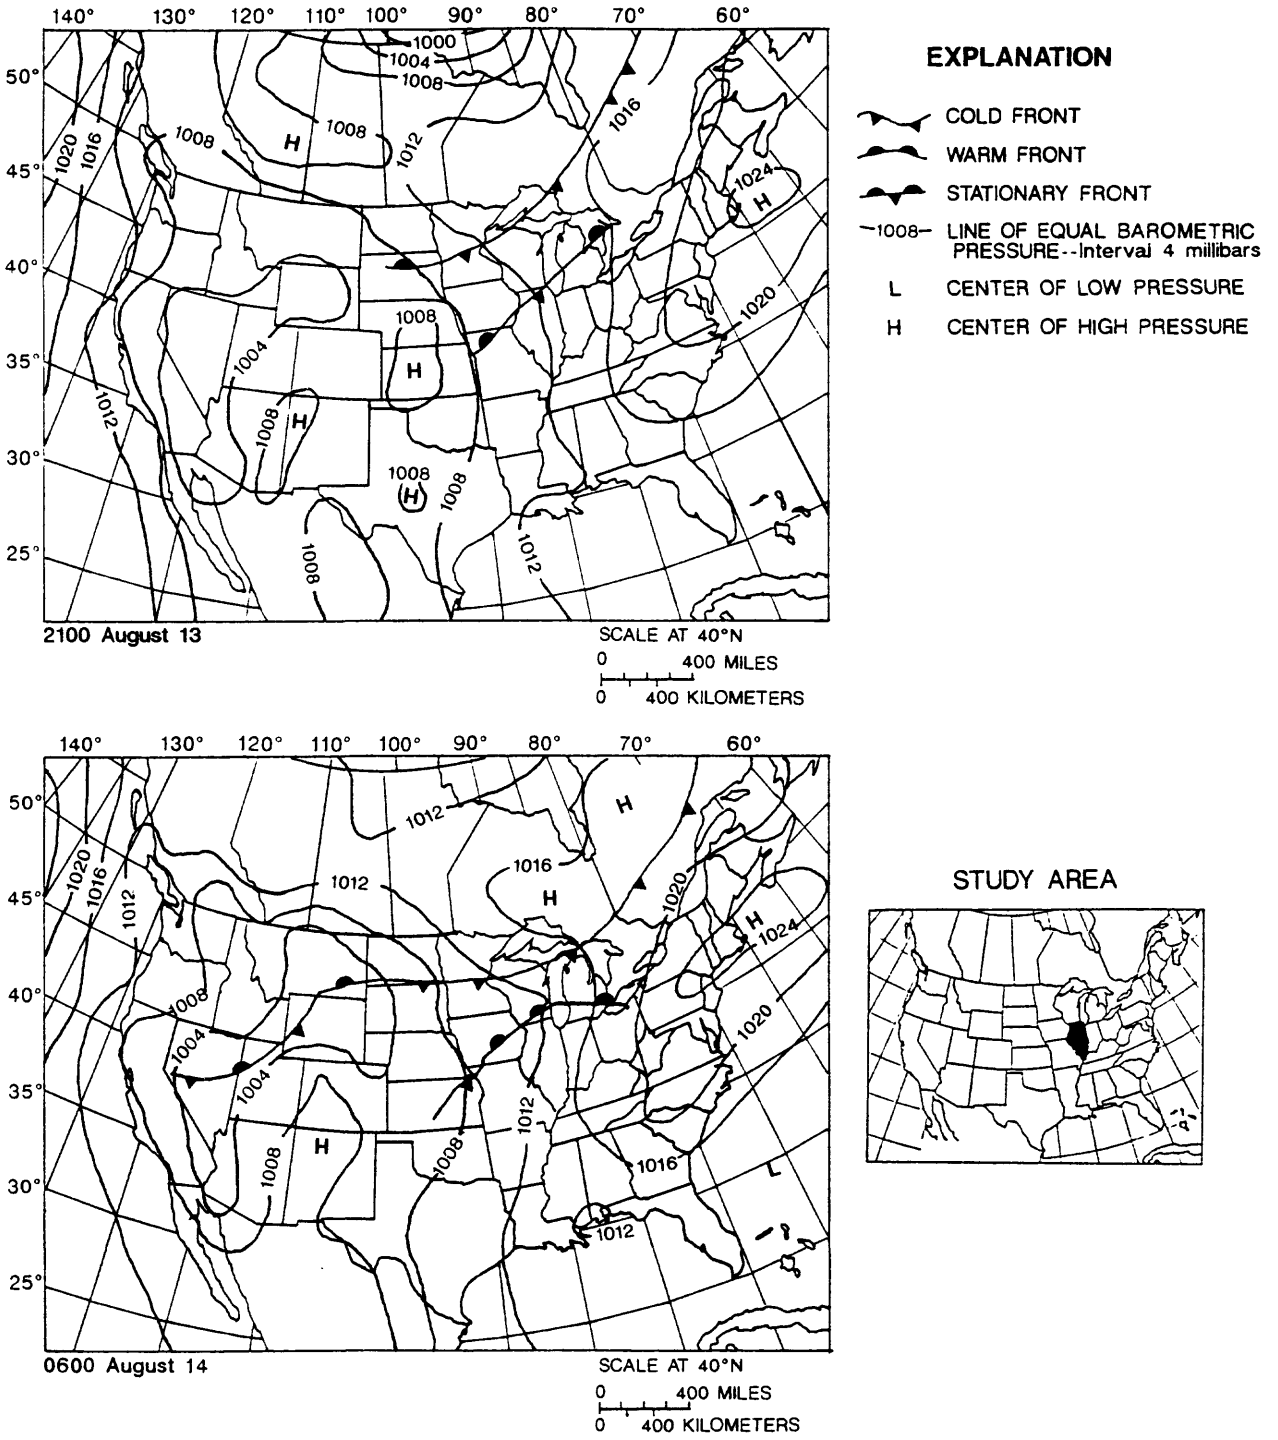

Figure 13.--Surface weather over the United States at 2100 hours central standard time on August 13 and at 0600 hours central standard time on August 14, 1987. (National Weather Service, written commun., 1988.)

The temperatures on both sides of the front were about 75°F; dewpoints were only 1-2°F lower south of the front but were as much as 10°F lower in the cold air mass north of the front. The warm air mass was at or near saturation as far as 6 mi above the Earth's surface. A short squall line of convective storms was moving northeastward from central Illinois (Merzlock, 1989, p. 11). This situation set the stage for rapid convective growth and heavy rainfall that began at 2115 hours c.s.t. on August 13; by 2130 hours c.s.t., the rain subsided. The second rainfall episode, which began at 0115 hours c.s.t. on August 14, was not accompanied by a major change in the surface weather; this episode ended at about 0230 hours c.s.t. The surface weather at 0600 hours c.s.t. on August 14 is shown in figure 13. Illinois continued to be in the warm saturated air mass. The final rainfall episode began at 0615 hours c.s.t. By about 0900 hours c.s.t., the convective forces leading to the heavy rainfall had begun to dissipate. Rainfall was light and scattered for the rest of the day.

Characteristics of Rainfall Distribution

Rainfall across the northern part of the State during August was 255 percent of normal in the northwest and 286 percent of normal in the northeast. Rainfall across the middle of the State was 132 percent of normal in the west, 113 percent of normal in the central part, and 171 percent of normal in the east. These above-normal percentages were largely the result of storms in the middle of the month and again at the end of the month (R.G. Semonin, Illinois State Water Survey, written commun., 1987).

During the period August 9-13, only 1-2 in. of rain fell in the northwestern part of the State. Elsewhere in the State, as much as 2.8 in. of rain fell at Chicago O'Hare International Airport (32), in the northeastern part; 3.39 in. fell at Quincy (139), in the western part; 0.69 in. fell at Normal (119), in the central part; and 1.67 in. fell at Kankakee (83), in the eastern part.

The temporal and spatial distributions of the storm rainfall indicate that the first showers of the storm period occurred in the northwestern and western parts of the State. Plots of cumulative rainfall (fig. 14) indicate that the early, scattered rainfall on August 13, in western Illinois, was of low intensity. By midafternoon, rainfall activity increased in the eastern and central parts of the State. At approximately 2015 hours c.s.t. on August 13, the first high-intensity storm hit northeastern Illinois with 2.51 in. of rainfall accumulation in just over an hour. Thunderstorms repeatedly formed over Du Page County and moved northeastward over Cook and southern Lake Counties. Heavy rain fell in three distinct periods starting at approximately 2115 hours c.s.t. on August 13, at approximately 0100 hours c.s.t. on August 14, and at approximately 0615 hours c.s.t. on August 14. About 3 in. of rain fell during each 1-2 hour period (fig. 14). By 1245 hours c.s.t. on August 14, Chicago O'Hare International Airport had received 9.35 in. of rain--an unprecedented amount in the 116 years of record--surpassing the city's previous 24-hour rainfall record of 6.24 in. (National Oceanic and Atmospheric Administration, 1987a, p. 27). The previous 24-hour record for Chicago was set on July 13, 1957 (Curtis, 1990, p. 49). The rainfall recurrence intervals for the 48-hour period of heaviest rainfall, for selected rainfall-gaging stations, are listed in table 4 (at back of report). Additional, unofficial data collected at rainfall-gaging stations

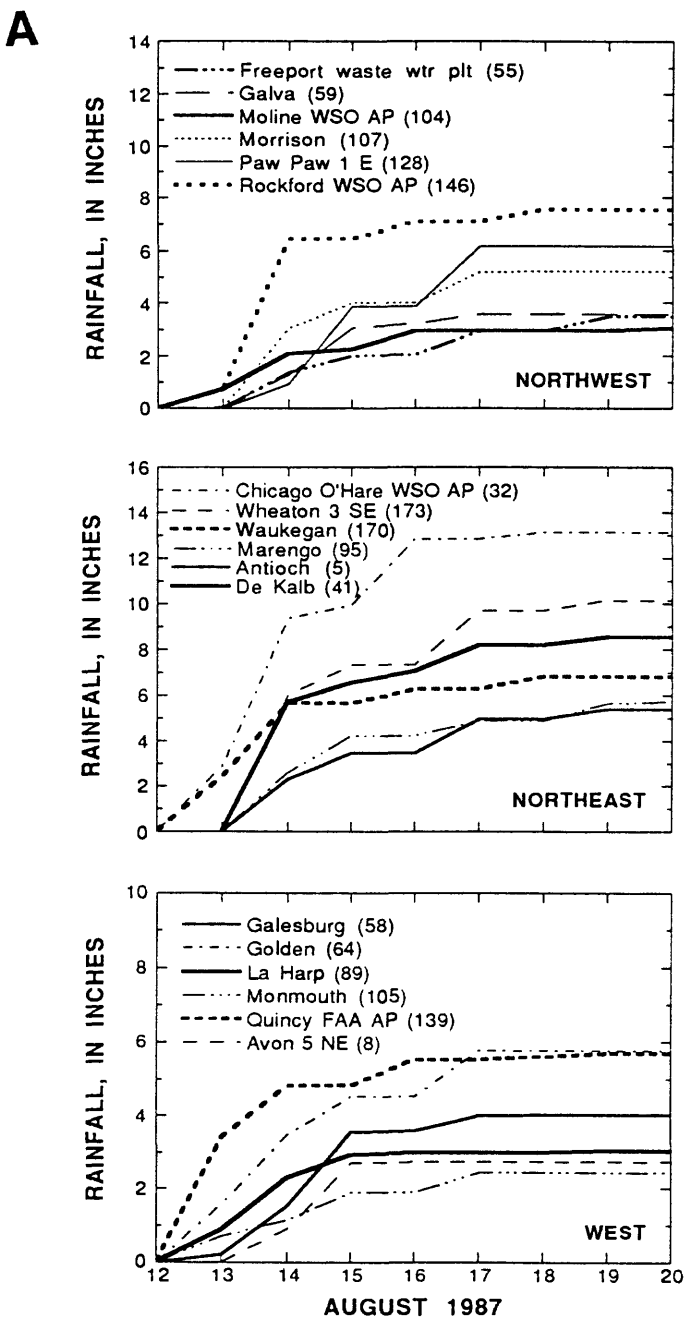

Figure 14.--Cumulative daily (A) and hourly (B) rainfall at selected rainfall-gaging stations in Illinois, August 12-20, 1987. (Numbers refer to locations in figure 1. Data from the National Oceanic and Atmospheric Administration, 1987b-g.)

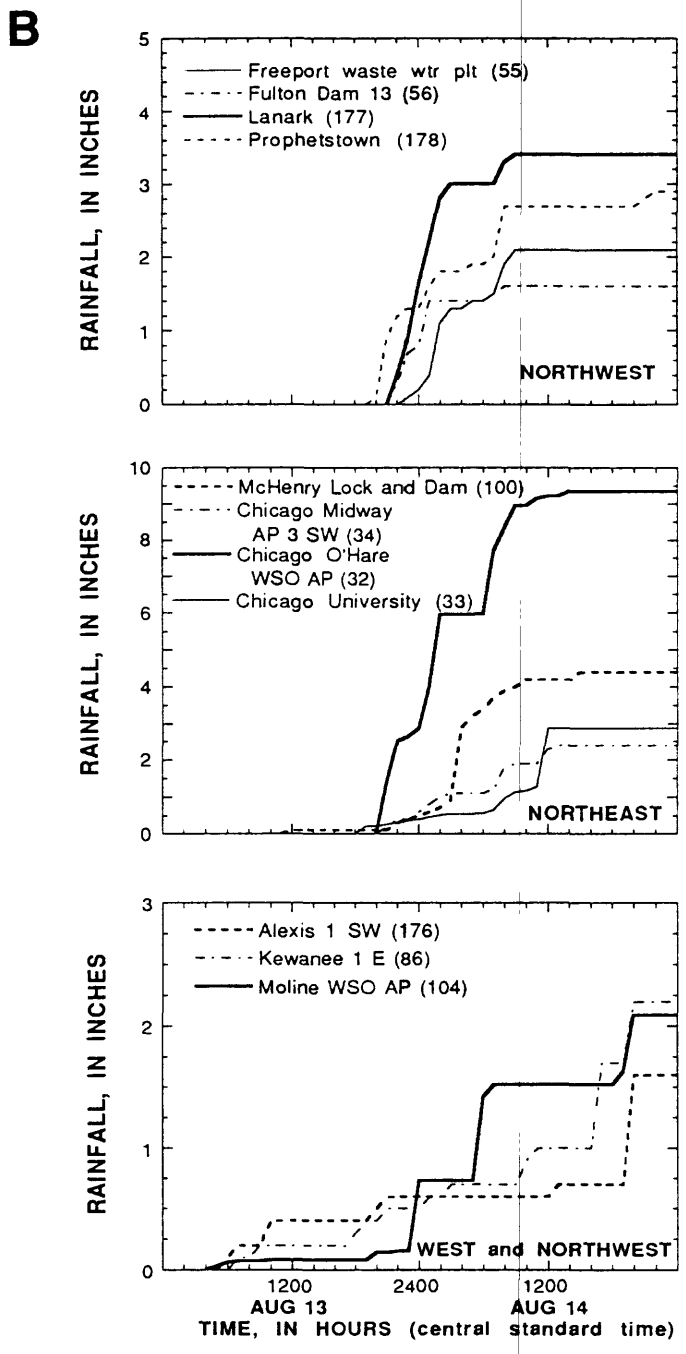

Figure 14.--Cumulative daily (A) and hourly (B) rainfall at selected rainfall-gaging stations in Illinois, August 12-20, 1987--Continued. (Numbers refer to locations in figure 1. Data from the National Oceanic and Atmospheric Administration, 1987b-g.)

not operated by the National Weather Service are presented in table 5 (at back of report) and figure 15. The methodology used to capture rain and record the rainfall at the unofficial sites may not be comparable in accuracy to National Weather Service methods.

The spatial distribution of the 2-day total storm rainfall is shown on plate 1B (in pocket). The greatest rainfall was in and near Rockford (146) in northwestern Illinois; and Chicago O'Hare International Airport (32), De Kalb (41), and Wheaton (173) in northeastern Illinois.

Description and Analysis of Floods

Within a year of the previous severe flood, major flooding again took place in the Des Plaines River basin. Peak discharges of record were recorded on McDonald Creek, Salt Creek, Addison Creek, and the Des Plaines River. Peak discharges of record also were established on North Branch Chicago River, Skokie River, and West Fork of North Branch Chicago River. In the Du Page River basin, peak discharges of record were recorded on West Branch Du Page River and St. Joseph Creek.

Other streams also were affected by the storms. Their peak stages and discharges, along with their respective RI's, are listed in table 6 (at back of report). The spatial distribution of the RI's is shown in figures 16 and 17. Unlike the 1986 flood previously described, the rainfall and flood RI's for this flood were similar.

Upper Mississippi River Basin Above The Illinois River

No peak discharges of record were recorded in the Rock River basin. The peak discharges that were recorded (RI's of 5 years or less) indicate that few streamflow-gaging stations were near the peak rainfall area.

Illinois River Basin

Eleven peak discharges of record in the Illinois River basin resulted from the storms of August 13-14. Recurrence intervals were greater than 100 years at 10 of those sites. The peak discharges were as much as 1.4 times greater than the 100-year flood discharge (Curtis, 1990, p. 50). All of the new peaks recorded in the Des Plaines River basin were either on the main stem or on tributaries to it. The peak discharge for the Des Plaines River near Gurnee (05528000), on August 14, was less than the annual flood (RI less than 2 years). Downstream, however, inflow from Buffalo Creek, which had a peak discharge of 717 ft^3/s (RI of 15 years) near Wheeling (05528500), increased the RI to 7 years at Des Plaines River near Des Plaines (05529000). The severe flooding along the lower reach of the Des Plaines River was caused by the large inflow of water from its tributaries downstream from Des Plaines.

At McDonald Creek near Mount Prospect (05529500), a discharge of 806 ft^3/s at a stage of 8.08 ft, the maximum for 36 years of record, was recorded on August 14. The previous maximum discharge was exceeded by 142 ft^3/s, and the

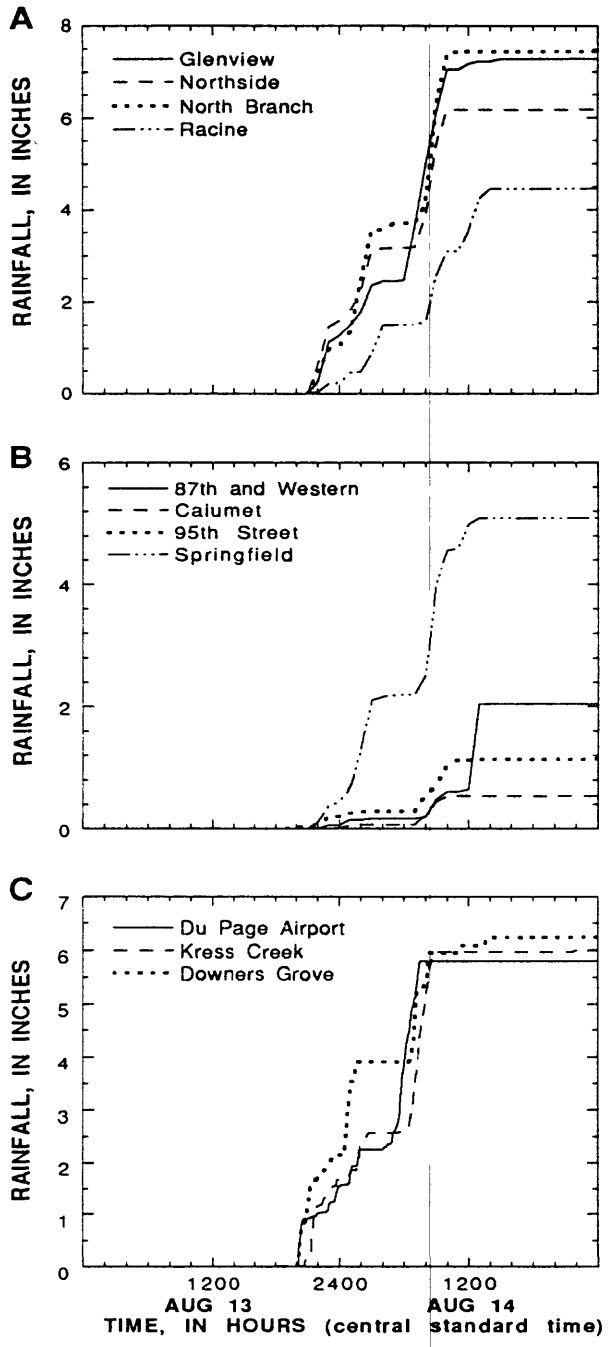

Figure 15.--Cumulative hourly rainfall at selected rainfall-gaging stations in Cook and Du Page Counties, Illinois, August 13-14, 1987. (Data for (A) and (B) from the Metropolitan Water Reclamation District of Greater Chicago, written commun., 1989; data for (C) from J.J. Duncker, U.S. Geological Survey, written commun., 1991.)

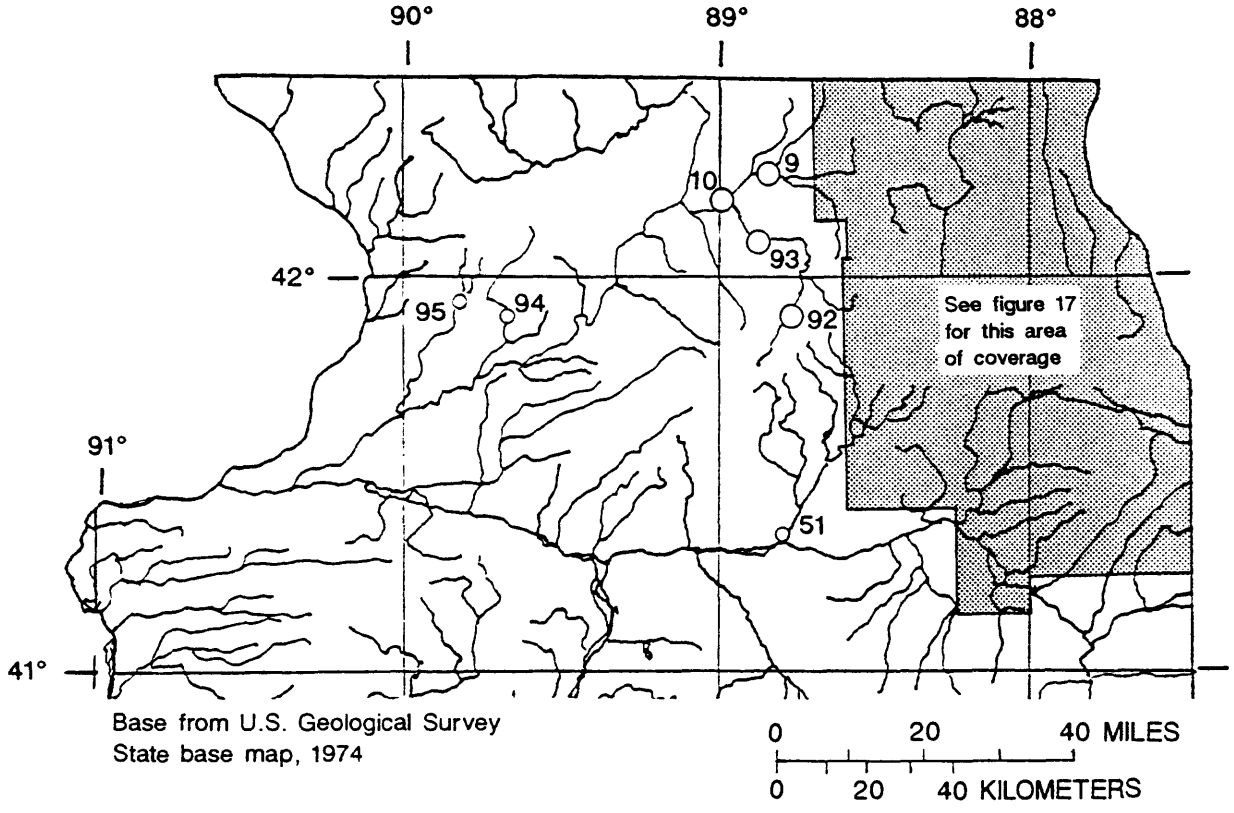

EXPLANATION

RECURRENCE INTERVAL OF FLOOD AT STREAMFLOW-GAGING STATIONS, IN YEARS

- ○ Less than 2
- ◯ 2-10

Figure 16.--Recurrence intervals for the floods of August 14-17, 1987, at selected streamflow-gaging stations in northern Illinois (numbers are referenced to table 6).

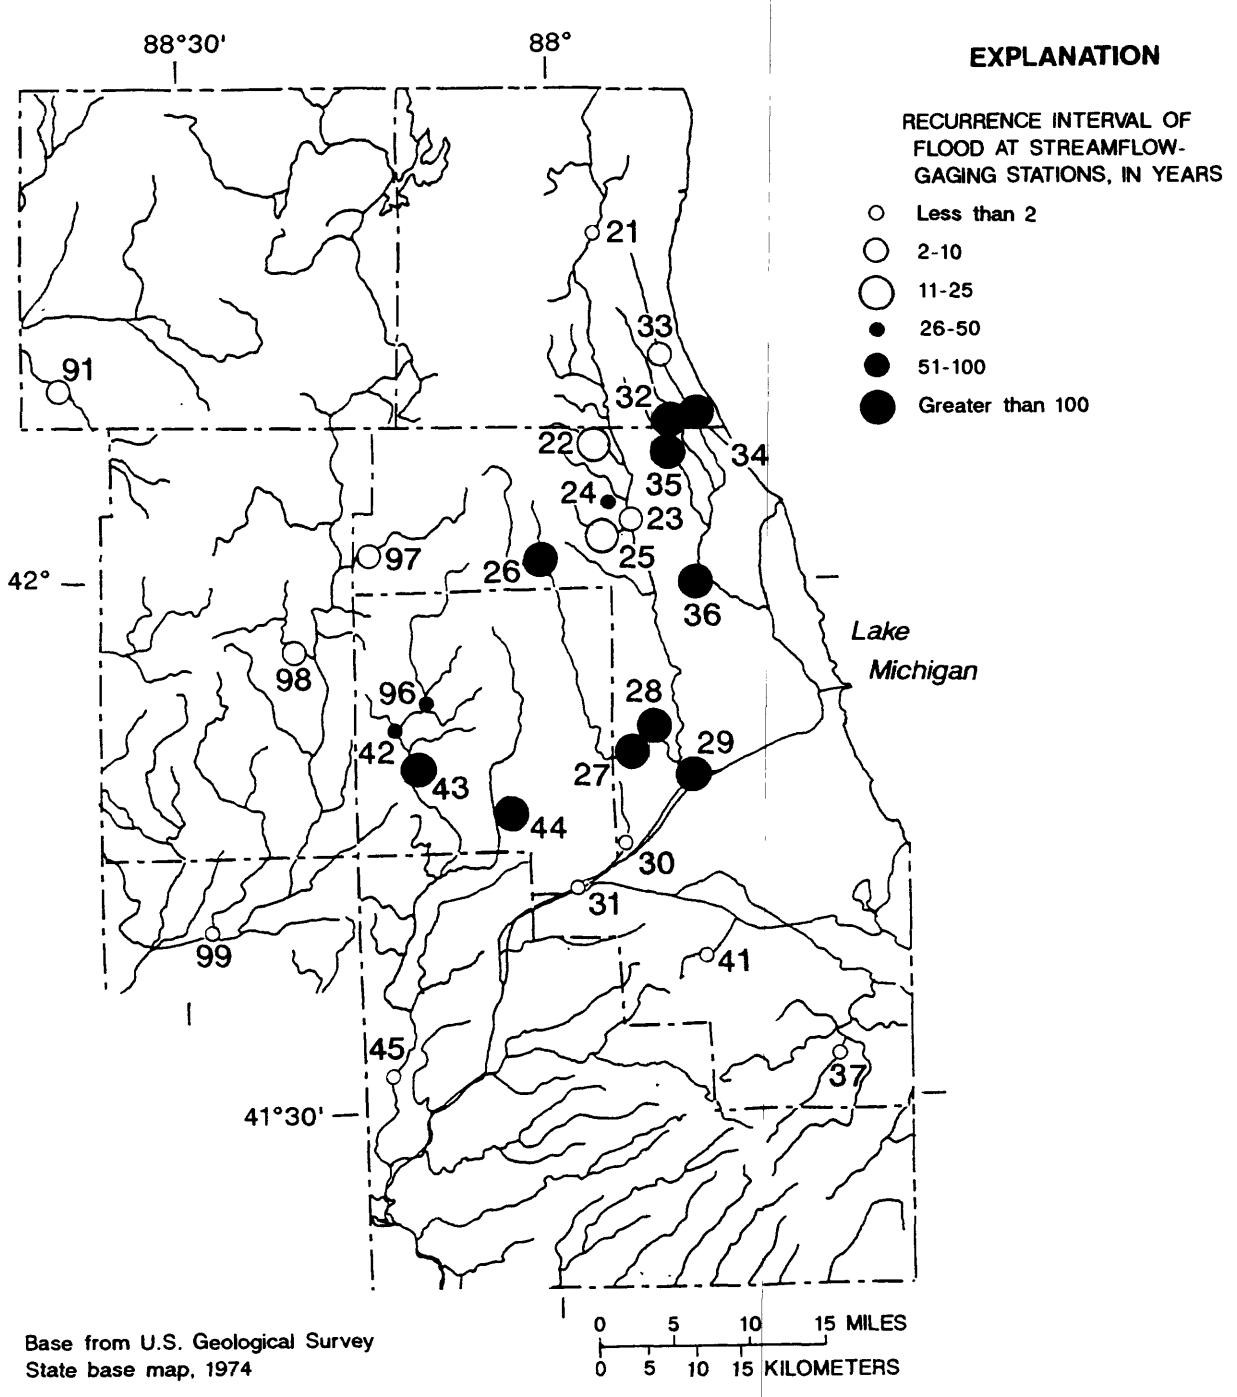

Figure 17.--Recurrence intervals for the floods of August 14-17, 1987, at selected streamflow-gaging stations in northeastern Illinois (numbers are referenced to table 6).

corresponding stage was exceeded by 0.50 ft; the RI was 50 years. Downstream, at Weller Creek at Des Plaines (05530000), the peak discharge of 1,490 ft^3/s on August 14 corresponded to an RI of 25 years. Salt Creek at Rolling Meadows (05530990) peaked at 1,650 ft^3/s (14.03 ft) on August 14. The peak discharge at Rolling Meadows corresponded to an RI 1.4 times greater than a 100-year RI (Curtis, 1990, p. 50) and exceeded the maximum for 14 years of record by 590 ft^3/s of discharge and 1.47 ft in stage. Downstream, at Western Springs (05531500), Salt Creek peaked at 3,230 ft^3/s, also on August 14; this peak discharge was the maximum for 42 years of record and also corresponded to an RI 1.4 times greater than the 100-year RI (Curtis, 1990, p. 50). Additional rains on August 16 caused Salt Creek at Western Springs to rise to 3,540 ft^3/s (10.54 ft), surpassing the new maximum for 42 years of record set 3 days earlier. Addison Creek at Bellwood (05532000) peaked on August 14 at 1,120 ft^3/s (12.84 ft). The peak discharge at Bellwood exceeded the maximum discharge for 37 years of record by 281 ft^3/s, and the corresponding stage was exceeded by 2.16 ft; the RI was greater than 100 years. The inflow from these tributaries resulted in a peak discharge of record, 9,770 ft^3/s (at 9.90 ft) on the Des Plaines River at Riverside (05532500) on August 15; the discharge corresponded to an RI 1.2 times greater than the 100-year RI (Curtis, 1990, p. 50). Station data for Buffalo Creek near Wheeling (05528500), McDonald Creek near Mount Prospect (05529500), Weller Creek at Des Plaines (05530000), Salt Creek at Rolling Meadows (05530990), Salt Creek at Western Springs (05531500), and Des Plaines River at Riverside (05532500) are listed in table 7 (at back of report). (Times given in table 7 are central daylight time rather than central standard time, which is used elsewhere in this report.) Streamflow hydrographs for selected sites in the Des Plaines River basin are shown in figure 18.

Peak discharges of record also were recorded at North Branch Chicago River at Deerfield (05534500) (933 ft^3/s at 11.52 ft) and at Niles (05536000) (2,590 ft^3/s at 11.35 ft) on August 14. Both discharges exceeded the 100-year RI and the previous maximums for 36 and 37 years of record, respectively. Peak discharges on tributaries to the North Branch Chicago River, Skokie River near Highland Park (05535070), and West Fork of North Branch Chicago River at Northbrook (05535500), also were peak discharges of record. At Skokie River near Highland Park (05535070), peak discharge was 895 ft^3/s (at 9.09 ft) on August 14. This peak discharge exceeded the 100-year RI and exceeded the maximum for 21 years of record by 171 ft^3/s; the corresponding stage was exceeded by 0.63 ft. About 6 mi upstream from Highland Park, however, the peak discharge of Skokie River at Lake Forest (05535000) corresponded to an RI of just 3 years, an indication of the extreme variability in storm rainfall. Station data for North Branch Chicago River at Deerfield (05534500), Skokie River near Highland Park (05535070), West Fork of North Branch Chicago River at Northbrook (05535500), and North Branch Chicago River at Niles (05536000) are listed in table 7.

Peak discharges of record also were recorded on tributaries to the Du Page River. Peak discharges on West Branch Du Page River near West Chicago (05539900) (958 ft^3/s) and on Kress Creek at West Chicago (05540060) (573 ft^3/s) correspond to 35-year RI's, but the floods of December 1982 and July 1964 were greater. Downstream, however, the peak discharges of West Branch Du Page River near Warrenville (05540095) on August 15 was a record 3,050 ft^3/s (at 5.85 ft) which exceeded the 100-year RI for 19 years of record. At St. Joseph Creek at Lisle (05540200), the peak discharge of 1,230 ft^3/s (at 8.10 ft) on August 14 nearly doubled the previous maximum for 18 years of record that had been recorded the

previous October. The Du Page River at Shorewood (05540500), the streamflow-gaging station farthest downstream, peaked at 3,650 ft^3/s on August 17, a peak equivalent to less than a 2-year RI. Station data for Kress Creek at West Chicago (05540060) are listed in table 7.

In the Fox River basin, no new peak discharges of record were recorded. The peak discharges that were recorded as a result of the August 13-14 storms had RI's that were 7 years or less.

SUMMARY

The storms of October 2-3, 1986, and August 13-14, 1987, in Illinois, though of contrasting types, both caused record floods and stream discharges with recurrence intervals exceeding 100 years. The storms of October 2-3, 1986, were associated with a cold front that stalled over northern and central Illinois from September 28-October 4. The storms varied in intensity and duration over a large area. The size of the resulting floods was due to the combined rainfall from the October 2-3 storms and 2 weeks of nearly daily rainfall that preceded the storms. The storms of August 13-14, 1987, were convective storms of short duration and high intensity over a limited area in northeastern Illinois. Antecedent rainfall was not an important factor in the resulting floods.

Meteorological and hydrological analyses of the storms are compiled in this report for the future reference of water-resource planners. The meteorological analyses include surface-weather maps showing the air mass and frontal conditions that produced the storms. The temporal and spatial distribution of the rainfall preceding and during the flooding is described by isohyetal maps and plots of cumulative daily and hourly rainfall. Hydrologic data and analyses include discharge hydrographs, streamflow data, frequency analyses of the peak discharges, and a comparison of peak stages and discharges for the floods to previous records.

The floods of September 26-October 4, 1986, included nine peak discharges of record, of which four exceeded the 100-year recurrence interval. The floods of August 14-17, 1987, produced 11 peak discharges of record, of which 10 exceeded the 100-year flood recurrence interval. The 1986 floods were scattered throughout the Illinois River basin and were most severe in northeastern Illinois. The floods of 1987 were localized and confined to the Des Plaines River basin. For the 1986 flood, the 3-day rainfall recurrence intervals were much smaller than the flood recurrence intervals, but the 10-day rainfall recurrence intervals were in close agreement. For the 1987 flood, the rainfall and flood recurrence intervals were in close agreement.

* New peak of record established during this flood.

[1] D, continuous discharge record; C, peak-stage and peak-discharge record only; D7, continuous discharge record for only 7 months of the water year; L, low flow only; FP, flood profile--peak-stage record only.

[2] Site and datum then in use.

[3] Ice affected.

[4] The estimate of >30,000 ft^3/s for station 05563000 is based on discharges for the 25-, 50-, and 100-year recurrence intervals that are 23,500, 28,500, and 33,900 ft^3/s, respectively (Curtis, 1987, p. 51)

e Estimated.
