The USGS, in cooperation with the Louisiana Department of Transportation and Development (2000), began a study in 1997 to evaluate the water quality of major rivers in the state. The study included the collection of water-quality data at 13 stations throughout the basin. Water samples were analyzed for a variety of constituents to detect potential water-quality problems. The study was conducted during the period of high summer temperatures and low-flow conditions. The comprehensive data base generated by this study provides background information that may be useful for other ongoing studies by other agencies and industries within the state and throughout the basin.
