CONVERSION FACTORS AND VERTICAL DATUM

<u>Multiply</u>	<u>By</u>	<u>To obtain</u>
foot	0.3048	meter
foot per mile	0.1894	meter per kilometer
inch	25.4	millimeter
mile	1.609	kilometer
million gallons per day	0.04381	cubic meter per second
cubic foot per second	0.02832	cubic meter per second
million cubic feet per day	0.3278	cubic meter per second
square mile	2.590	square kilometer
foot squared per day	0.0929	meter squared per day

Sea level: In this report “sea level” refers to the National Geodetic Vertical Datum of 1929 -a geodetic datum derived from a general adjustment of the first-order level nets of both the United States and Canada, formerly called Sea Level Datum of 1929.

LOCATION AND DEPTH OF SAND AND CLAY INTERVALS IN JACKSON COUNTY, MISSISSIPPI

By Eric W. Strom and William T. Oakley

ABSTRACT

Driller's logs and geophysical logs from various sources were used to compile information on the location and depth of water-bearing sands and intervening clays in Jackson County, southeastern Mississippi. Each log was checked for accuracy of location and for adequate description of subsurface materials. Generally, data for sand intervals greater than about 20 feet in thickness and less than 2,000 feet below land surface were compiled. Data from more than 1,600 logs were compiled. Well logs generally showed two or three sand intervals, but as many as seven were reported. Compiled sand intervals averaged about 48 feet in thickness, and well depths averaged about 417 feet below land surface. Data determined from each log were entered into a geographic information system (GIS) data base. A graphical representation of each well log is presented.

INTRODUCTION

Jackson County, located on the Gulf Coast in southeastern Mississippi, is experiencing rapid economic and industrial growth (fig. 1). Continued growth in the area depends on the availability of an adequate supply of water. In 1994, the U.S. Geological Survey (USGS), in cooperation with the Jackson County Board of Supervisors, began an investigation to compile information on the location and depth of water-bearing sands and intervening clays in Jackson County. This information is beneficial to city planners, engineers, water managers, water-well contractors, real estate developers, industries, and consultants, as well as to scientists investigating the nature and distribution of the sediments.

The location and depth of sand and clay intervals were determined from selected well logs in Jackson County, Mississippi. This report presents the data in graphical and tabular formats with accompanying maps showing well locations.

The study area is Jackson County (fig. 1), which is located in the Gulf Coastal Plain physiographic province (Fenneman, 1938). Topographic relief generally is low, ranging from sea level at the coast to nearly 200 feet above sea level in northern parts of the county. Geologic units in the study area range from Miocene to Holocene in age (table 1) and generally dip south-southwestward. These units consist mostly of clay, silt, sand, and gravel.

METHODOLOGY

Geophysical and drillers' logs of wells were used to determine the information presented in this report. Drillers' well logs are submitted, in accordance with Mississippi law, to the Mississippi Department of Environmental Quality (DEQ), Office of Land and Water Resources (OLWR), and contain a description of the subsurface materials penetrated. Thousands of well logs are on file for Jackson County. Most are drillers' logs; however, some logs have inadequate descriptions of location or subsurface materials. The logs selected in the investigation were checked for adequate information, verified against county ownership maps, plotted on 7.5-minute topographic maps, and checked for correct landnet location. Sites were field located where geophysical, water-quality, or water-level data were previously collected by USGS or DEQ personnel. A total of 1,603 well logs (252 geophysical logs and 1,351 drillers' logs) were selected for inclusion in this report.

Most of the subsurface materials reported on the drillers' well logs were either sand or clay. For this investigation, sand is used to indicate aquifer type material (fine to coarse sand and gravel); clay is used to indicate confining material (clay and silt). Examples of clay and sand intervals interpreted from a geophysical log and from a driller's log are shown in figure 2. Generally, sand intervals greater than about 20 feet in thickness and less than 2,000 feet below land surface were compiled in the investigation. Data determined from each log were entered into a geographical information system (GIS) data base.

RESULTS

Generally well logs showed two or three sand intervals, but as many as seven sand intervals were reported. Compiled sand intervals averaged about 48 feet in thickness, and well depths

averaged about 417 feet below land surface. The sand intervals from drillers' logs cannot be verified; therefore, accuracy is variable. Sand intervals from the geophysical logs were determined during this investigation. Graphical representations of each of the 1,603 well logs are presented by well identifier in alphanumerical order (fig 3.). Additional information for each well log is listed in table 2. Locations of the wells are shown on plates 1-4.

Table 1. Geologic units and principal aquifers in the study area (modified from Colson and Boswell, 1985)

Erathem	System	Series	Geologic unit	Lithology	Hydrogeologic properties
Cenozoic	Quaternary	Holocene	Alluvial deposits	Clay, silt, sand, and fine gravel	Contains saltwater probably as far north as saltwater encroaches up the rivers.
		Pleistocene	Terrace deposits	Sand and clay grading downward into coarse sand and fine gravel	Contains freshwater near the coast at shallow depths. Subject to salt-water encroachment.
		Pleistocene or Pliocene	Citronelle Formation	Sand and gravel	Maintains high base flows of streams. Source of recharge to the Miocene aquifer system. Supplies upland rural wells.
	Tertiary	Pliocene	Graham Ferry Formation	Gray, carbonaceous, and fossiliferous clay and lenticular sand, occasionally coarse, usually fine to medium	Supplies much of the ground water for municipal and industrial use.
			Pascagoula Formation	Clay, shale, and sand. Sand is usually lenticular, fine to very coarse	Comprises several aquifers along the coast and many sand beds of local extent. Base of freshwater is in the lower part of the formation.
		Miocene	Hattiesburg Formation	Clay and sand similar to the Pascagoula Formation	Contains supplies of freshwater in counties to the north.
			Catahoula Formation	Sand, shale, and sandstone	Unused. Saltwater.
