## Definitions

**Classified stream** is a stream listed on the Kansas Surface Water Register that is regulated by the Kansas Department of Health and Environment.

**Climatic year** is the 12-month period January 1 through December 31.

**Controlled stream segment** is a stream segment affected by releases from large reservoirs.

**Unclassified stream** is a stream not listed on the Kansas Surface Water Register that is not regulated by the Kansas Department of Health and Environment.

**Uncontrolled stream segment** is a stream segment not affected by releases from large reservoirs.

**Water year** is the 12-month period October 1 through September 30. The water year is designated by the calendar year in which it ends. Thus, the year ending September 30, 2000, is called the “2000 water year.”

# Estimates of Median Flows for Streams on the Kansas Surface Water Register

By Charles A. Perry, David M. Wolock, and Joshua C. Artman

## Abstract

The Kansas State Legislature, by enacting Kansas Statute KSA 82a–2001 et. seq., mandated the criteria for determining which Kansas stream segments would be subject to classification by the State. One criterion for the selection as a classified stream segment is based on the statistic of median flow being equal to or greater than 1 cubic foot per second. As specified by KSA 82a–2001 et. seq., median flows were determined from U.S. Geological Survey streamflow-gaging-station data by using the most-recent 10-years of gaged data (KSA) for each streamflow-gaging station. Median flows also were determined by using gaged data from the entire period of record (all-available hydrology, AAH).

Least-squares multiple regression techniques were used, along with Tobit analyses, to develop equations for estimating median flows for uncontrolled stream segments. The drainage area of the uncontrolled gaging stations used in the regression analyses ranged from 2.06 to 12,004 square miles. A logarithmic transformation of the data was needed to develop the best linear relation for computing median flows. In the regression analyses, the significant climatic and basin characteristics, in order of importance, were drainage area, mean annual precipitation, mean basin permeability, and mean basin slope. Tobit analyses of KSA data yielded a root mean square error of 0.285 logarithmic units, and the best equations using Tobit analyses of AAH data had a root mean square error of 0.247 logarithmic units.

These equations and an interpolation procedure were used to compute median flows for the uncontrolled stream segments on the Kansas Surface Water Register. Measured median flows from gaging stations were incorporated into the regression-estimated median flows along the stream segments where available. The segments that were uncontrolled were interpolated using gaged data weighted according to the drainage area and the bias between the regression-estimated and gaged flow information. On controlled reaches of Kansas streams, the median flow information was interpolated between gaging stations using only gaged data weighted by drainage area.

Of the 2,232 total stream segments on the Kansas Surface Water Register, 30 percent of the segments had an estimated median streamflow of less than 1 cubic foot per second when the KSA analysis was used. When the AAH analysis was used, 40 percent of the segments had an estimated median streamflow of less than 1 cubic foot per second.

## INTRODUCTION

The expected amount and historical range of flow in Kansas streams are important considerations for the classification, evaluation, and regulation of water supplies, recreation, aquatic life habitat, and pollution control within the State. Kansas Statute KSA 82a–2001 et. seq. (see Appendix A) specifically mentions median streamflow as one criterion for classifying streams. Current water-quality regulations in Kansas apply numeric water-quality criteria to the 2,232 stream segments listed on the Kansas Surface Water Register. The

register is maintained by the Kansas Department of Health and Environment (KDHE) and is used to identify designated uses of stream segments. Numeric water-quality criteria for the stream segments are based on assigned designated uses.

KSA 82a–2001 et. seq. defines one criterion for a classified stream segment as having a median flow of 1 ft<sup>3</sup>/s or greater. Other criteria include whether a stream segment contains a wastewater discharge, contains threatened or endangered species, or has a cost/benefit ratio less than 1 where median streamflows are 0 ft<sup>3</sup>/s. Median flow statistics for stream segments are based on daily flow data collected by the U.S. Geological Survey (USGS) at 214 streamflow-gaging stations with 10 or more years of record located throughout Kansas and surrounding States (fig. 1). The current and historical streamflow information collected by the USGS provides a resource for estimating the expected amount and range of streamflow throughout the State. The measured streamflow record can be used to define statistics that summarize historical streamflow amounts at each stream gage. These statistics then can be related to the physical characteristics of the drainage basins that contribute to measured flow at the gage. Furthermore, a statistical model that is based on these relations can be used to estimate streamflow statistics for ungaged stream segments. Therefore, information on median flow characteristics is needed for streams in Kansas.

To address this need, a study of median flows for Kansas streams was conducted by the USGS in cooperation with KDHE. Streamflow data used in this study were collected by the USGS (Putnam and others, 2001) through other cooperative studies with various government agencies.

## Purpose and Scope

The purpose of this report is to document the methods and results of a study designed to estimate the median flow (50-percent flow duration) for the downstream end of each stream segment listed on the Kansas Surface Water Register. Median flow for each stream segment was determined from gaged-location streamflow records or was estimated from statewide regression models. This report documents development of regression models to estimate median flow from climatic and basin characteristics. The report describes application of the drainage-area ratio method and the regression models to estimate the median flows for

Kansas Surface Water Register stream segments, the interpolation of estimates for ungaged segments, and the Internet dissemination of results and a geographic-information-system (GIS) database.

Two different statistical analysis were performed on uncontrolled flows measured at 149 gaging stations. According to language in KSA 82a–2001 et. seq., only the most-recent 10 years of streamflow data for each gaging station were to be used for statistical analysis. This analysis was termed the KSA analysis. The entire period of record also was used for analysis of median flows, and this analysis was termed the all-available hydrology (AAH) analysis.

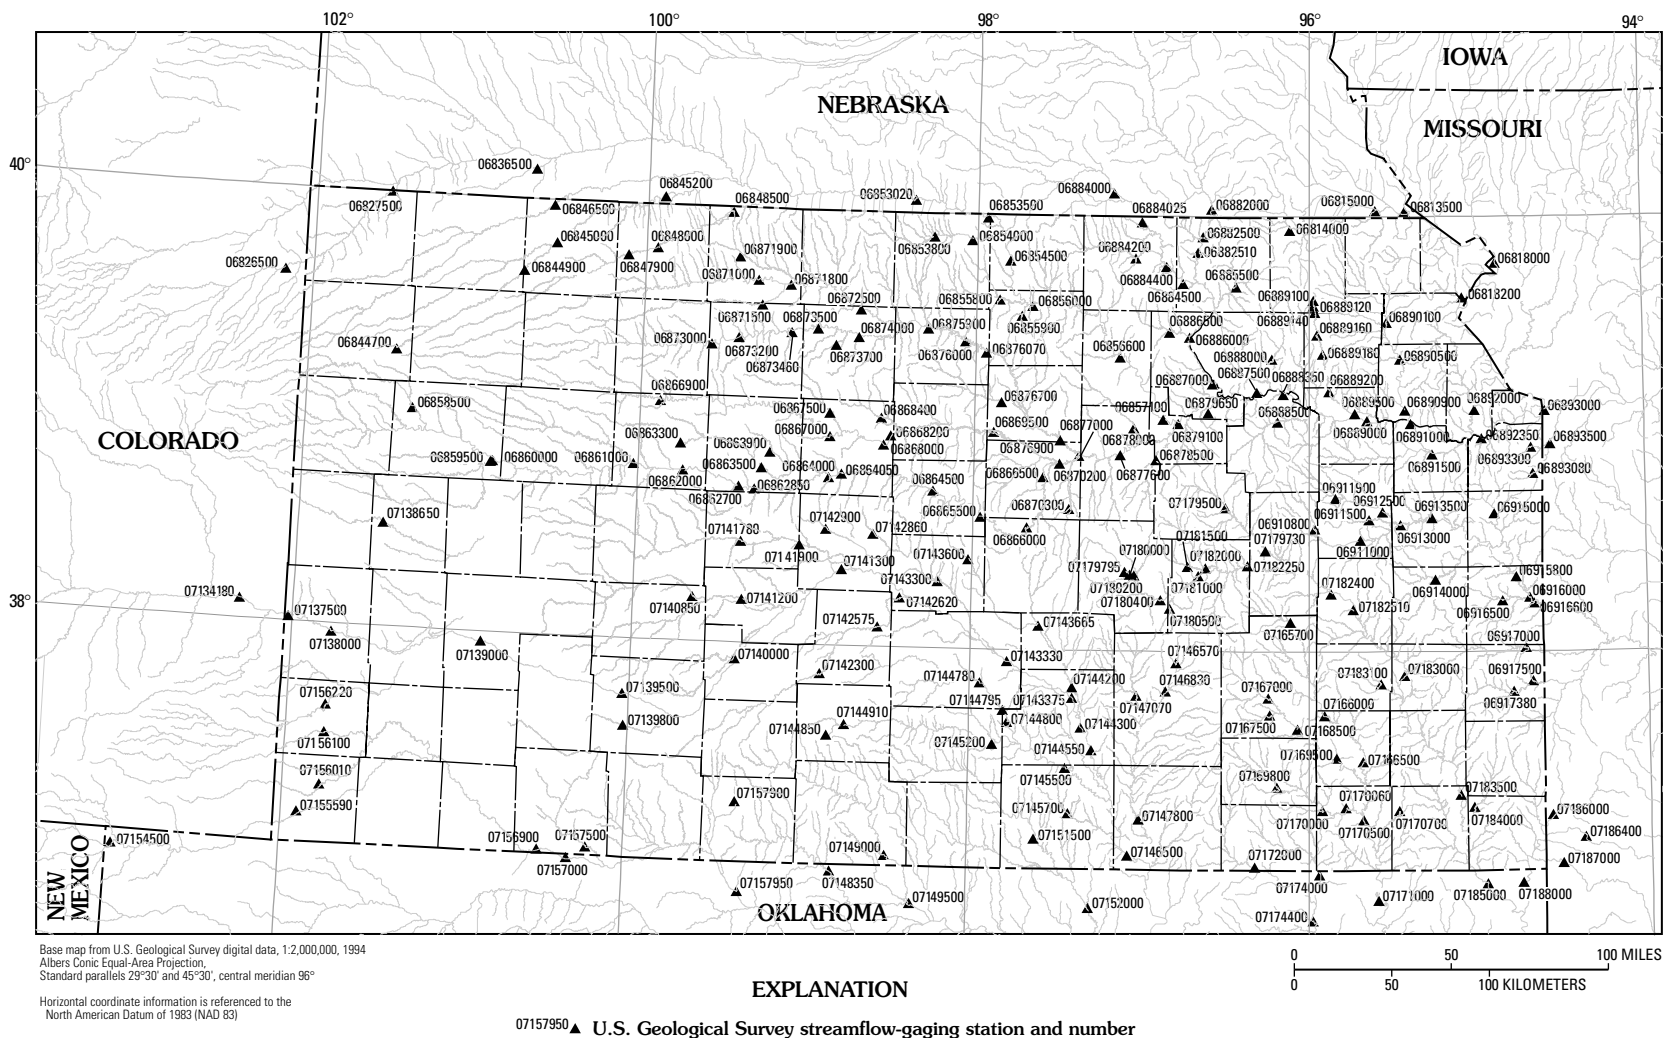

The information contained in this report can be used by State agencies and others to help in the effective management of Kansas surface-water resources. Optimal reservoir operations, legally distributed in-stream withdrawals, and water-quality concerns are issues directly linked to median streamflows. The methods described herein can be applied nationwide using USGS streamflow data that are available throughout the United States.

## Previous Studies

Previous low-flow and flow-duration studies for Kansas include an investigation by Furness (1959) who developed a method for estimating flow-duration curves for ungaged sites that was based on regionalized flow-duration data from 122 continuous-record, streamflow-gaging stations with drainage areas of between 100 and 3,000 mi<sup>2</sup> for the period 1921–56. Maps were developed showing a variety of statewide low and mean streamflow maps. Furness (1959) also noted that the low-flow parts of the flow-duration curves could be verified or improved by relating base-flow measurements at the ungaged site to base-flow measurements at a nearby, index streamflow-gaging station.

Jordan (1983) updated the maps developed by Furness by including additional streamflow-gaging stations and data for the period 1957–76. Jordan's study included a map that depicted the areas of Kansas where the median streamflow for a 500-mi<sup>2</sup> basin was greater than 0.1 ft<sup>3</sup>/s.

Two studies by Studley (2000, 2001) evaluated the application of the Furness method to ungaged stream sites in Kansas using nearby streamflow-gaging stations as index stations. The results of these two recent studies indicated that the Furness method continues to

**Figure 1.** Location of U.S. Geological Survey streamflow-gaging stations in Kansas and parts of surrounding States with 10 or more years of record that were used to estimate median flows.

be a useful tool for estimating flow-duration curves for ungaged sites and that the method could be used for sites with drainage areas less than 100 mi<sup>2</sup>.

Many studies have been conducted to evaluate low flow from regression equations that relate low flow to basin characteristics. In a recent USGS study (Ries and Friesz, 2000), basin characteristics were determined from digital map data, and flow statistics were computed for individual stream segments using GIS techniques. Ries and Friesz (2000) used the drainage-area ratio method to compute streamflow characteristics for stream segments that had between 0.5 and 1.5 times the drainage area of streamflow-gaging stations on the same stream. Many States have used regression analysis to regionalize low-flow frequency statistics including New Hampshire, Rhode Island, and Vermont (Johnson, 1970); Pennsylvania and New York (Ku and others, 1975); Maine (Parker, 1977); Massachusetts (Male and Ogawa, 1982; Vogel and Kroll, 1990; Risley, 1994; Ries and Friesz, 2000); Montana (Parrett and Hull, 1985); Indiana (Arihood and Glatfelter, 1991); and central New England (Wandle and Randall, 1994).

## **FACTORS AFFECTING STREAMFLOW**

### **Physical Setting**

Physiographically, Kansas is located almost entirely within the Interior Plains as described by Schoewe (1949). A description of the hydrologic characteristics of the physiographic provinces within the Interior Plains is beyond the scope of this report, but the fact that there are significant variations denotes the complex nature of and difficulty in attempting to define flow characteristics across Kansas.

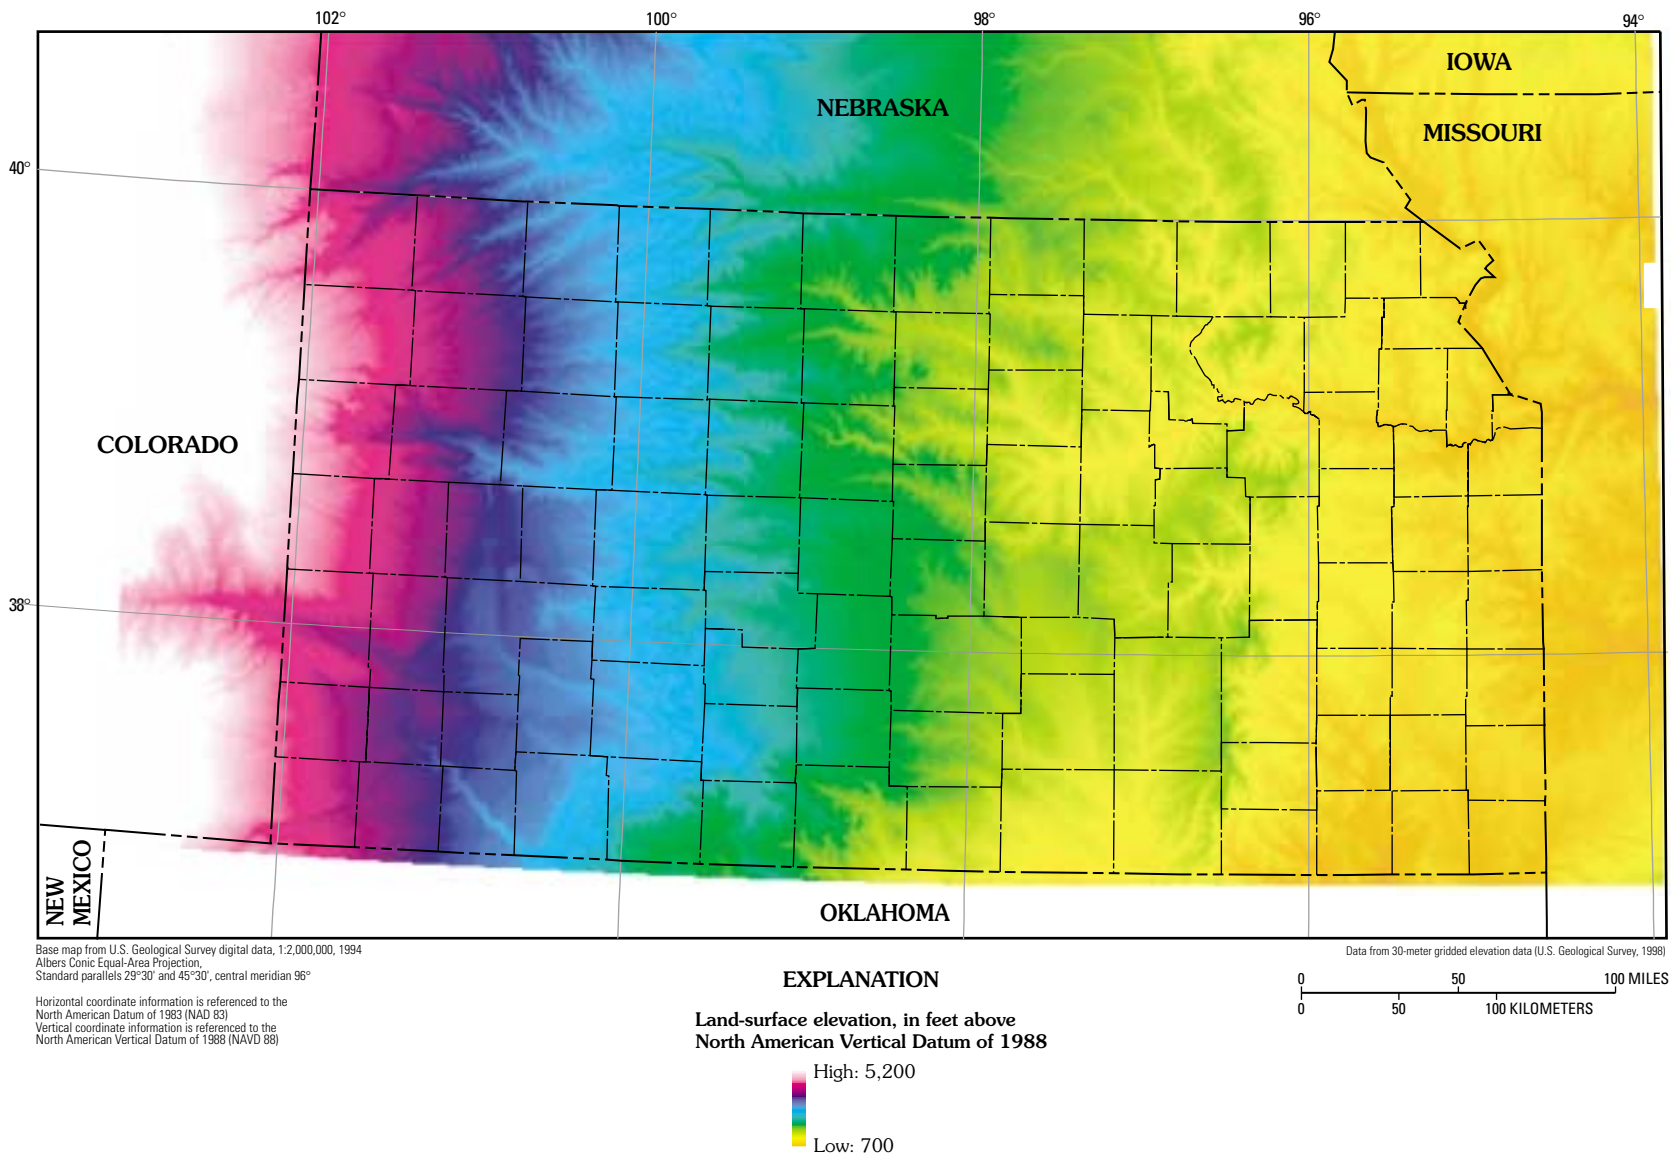

The topography of the western two-thirds of the State is typical of the High Plains region and is characterized by flat or gently sloping surfaces with little relief. The topography of the eastern one-third of the State is more variable, with alternating hills and lowlands. Land-surface elevations within the State range from about 700 ft above the North American Vertical Datum of 1988 (NAVD 88) at the Kansas-Oklahoma State line in southeast Kansas to about 4,135 ft above the NAVD 88 at a point near the Kansas-Colorado State line in western Kansas—a vertical difference of about 3,435 ft (fig. 2). The average land-surface slope for Kansas (fig. 3) using 30-m grid elevation data is about 1.9 degrees.

Other physical characteristics affecting the flow characteristics of watersheds are the types of soils and land-use and treatment practices within the basin. For example, with all other factors being equal the low-flow potential from watersheds with soils of low permeability (fig. 4) is less than that from watersheds where highly permeable soils tend to allow greater infiltration and a greater ground-water contribution to base flow of the stream. The western two-thirds of the State typically has soils of moderate to high permeability, whereas the eastern one-third has soils of lower permeability. Land-treatment practices, such as contour farming and construction of water-retention structures, can increase the amount of infiltration of runoff to ground water, which ultimately returns to stream channels as base flow. However, land-treatment practices are difficult to assess and apply to the various types of basins statewide.

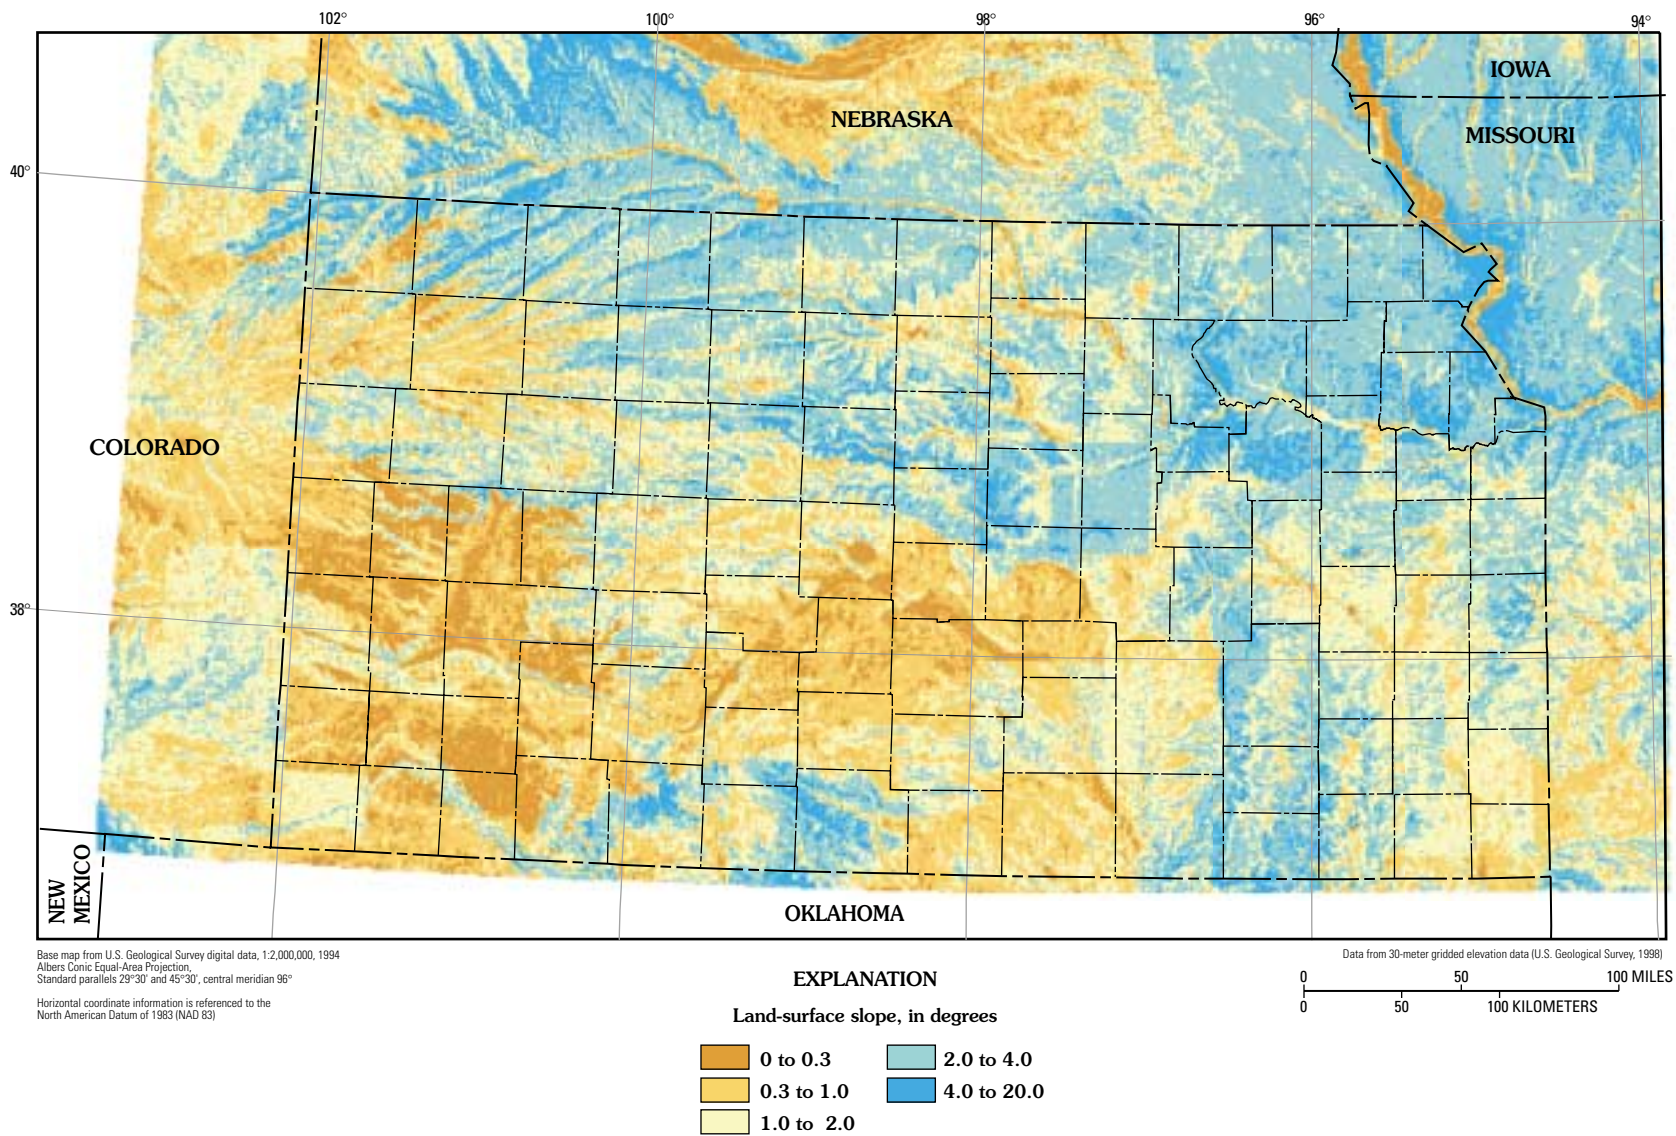

### **Climatic Characteristics**

The climate of Kansas is affected by the movement various air masses of tropical and continental origin over the open, inland plains, and seasonal precipitation extremes are common. About 70 percent of the mean annual precipitation falls from April through September. Precipitation during early spring and late fall occurs in association with frontal air masses that produce low-intensity rainfall of regional coverage. During the summer months, the weather is dominated by warm, moist air from the Gulf of Mexico or by hot, dry air from the Southwest. Summer precipitation generally occurs as high-intensity thunderstorms.

Watersheds in Kansas exhibit a wide range of climatic characteristics that affect streamflow. Generally, precipitation varies in an east-west direction, with little north-south variation. The general climate of the western part of Kansas is semiarid with hot, dry summer months and cold, windy winter months. The eastern part of the State tends to be more humid, with sultry summer months and cold, damp winter months. Mean annual precipitation, the major climatic factor affecting streamflow in the State, varies from about 16 in. in extreme western Kansas to about 42 in. in southeastern Kansas (Daly and others, 1997) (fig. 5). Mean annual precipitation at 149 streamflow-gaging stations used in the regression analyses for uncontrolled stream segments on the Kansas Surface Water Register is given in table 1.

<sup>1</sup>The Kansas Surface Water Register is maintained by the Kansas Department of Health and Environment (Topeka).<sup>2</sup>Mean annual precipitation for each gaging station from Daly and others (1997).<sup>3</sup>Mean basin permeability for each gaging station from U.S. Department of Agriculture (1994).<sup>4</sup>Mean basin slope for each gaging station from U.S. Geological Survey (1998).

## Basin Characteristics

Basin characteristics used in the analyses were selected on the basis of their theoretical relation to differences in flow magnitudes of streams, results of previous studies in similar hydrologic environments, and on the ability to measure them. The basin characteristics considered in this report included drainage area, in square miles; mean basin elevation, in feet above NAVD 88; mean basin permeability, in inches; mean basin slope, in degrees; a Base Flow Index (Wahl and Wahl, 1995); mean annual runoff for hydrologic basins in the United States, in cubic feet per second (Gebert and others, 1987); and runoff from the PRISM model (parameter-elevation regressions on independent slope model), in cubic feet per second, using the mean annual precipitation grid for the United States developed by Daly and others (1994). The mean annual runoff reflects the difference between precipitation and evapotranspiration. Selected basin characteristics for the 149 streamflow-gaging stations used in the regression analyses for uncontrolled stream segments are provided in table 1.

All basin characteristics were measured from digital-map data using automated GIS procedures. The automated procedure was created using the AML programming language of the ARC/INFO GIS software (Environmental Systems Research Institute, Inc., 1991). The automated procedure determines the drainage-basin boundary at the gaging station or for the downstream end of a stream segment and creates a digital data layer of the basin boundary, then overlays the boundary on the other digital data layers to determine the other basin characteristics for the station or segment. The grid values then are averaged for the area within the drainage basin.

## METHODS FOR ESTIMATING MEDIAN FLOWS

Climatic and basin characteristics were used in the analyses of median flows at gaged and ungaged sites on controlled and uncontrolled streams. For this study, ARC/INFO GIS software was used to estimate climatic and basin characteristics. Many spatial data sets were available for this task, including: (1) 30-year (1961–90) mean annual precipitation data (Daly and others, 1997), (2) 30-m gridded elevation data (U.S. Geological Survey, 1998) for determining drainage area, mean basin slope, and mean basin elevation, and

(3) STATSGO soil-permeability data (U.S. Department of Agriculture, 1994).

The flow information was derived from 216 gaging stations in Kansas and the surrounding States with at least 10 years of streamflow record. Streamflow at 149 of the stations on uncontrolled stream segments were included in the regression analyses. The flows of uncontrolled stream segments are unaffected by storage and release from large upstream reservoirs. One hundred thirty-one streamflow-gaging stations in Kansas and 18 in surrounding States (four in Missouri, five in Nebraska, and nine in Oklahoma) measured uncontrolled flow. All available records through water year (October through September) 2000 were used to compute the streamflow statistics for these gaging stations. Names and descriptions of the streamflow-gaging stations used in measuring flow at uncontrolled sites are listed in table 1.

Three gaging stations in Kansas that measured uncontrolled flow and had at least 10 years of record were not included in the regression analyses. One station, Indian Creek at Overland Park (station 06893300), was not used because it is affected by extensive urbanization. Two other stations, Beaver Creek at Cedar Bluffs (station 06846500) and Paradise Creek near Paradise (station 06867500), were not used because streamflow statistics were not consistent with the other stations statistics.

## Gaged Stream Sites

The USGS has established standard methods for estimating flow duration (Searcy, 1959) for streamflow-gaging stations. The computer software programs IOWDM, ANNIE, and SWSTAT were used to format input data, manage and display data, and complete the flow-duration statistical analyses (Lumb and others, 1990; Flynn and others, 1995). These programs are available on the World Wide Web at [http://water.usgs.gov/software/surface\\_water.html](http://water.usgs.gov/software/surface_water.html)

Daily mean flows for all complete water years of record were used to determine flow-duration statistics for continuous-record, streamflow-gaging stations. The water year begins on October 1 and ends on September 30 of the following year. Daily mean flows for USGS streamflow-gaging stations in Kansas are available on the World Wide Web at <http://waterdata.usgs.gov/ks/nwis/>

A flow-duration curve is a graphical representation of the percentage of time streamflows for a given time

step (usually daily) are equaled or exceeded over a specified period (usually the complete period of record) at a stream site. Flow-duration curves usually are constructed by first ranking all of the daily mean discharges for the period of record at a gaging station from largest to smallest, next computing the probability for each value of being equaled or exceeded, then plotting the discharges against their associated exceedance probabilities (Loaiciga, 1989, p. 82). The daily mean discharges are not fit to an assumed distribution. Flow-duration analysis can be done by use of the USGS software described previously or by use of commercially available statistical software.

Flow-duration statistics are points along a flow-duration curve. For example, the 99-percent duration streamflow is equaled or exceeded 99 percent of the time, whereas the 50-percent duration streamflow is equaled or exceeded 50 percent of the time. Strictly interpreted, flow-duration statistics reflect only the period for which they are calculated; however, when the period of record used to compute the statistics is sufficiently long, the statistics often are used as an indicator of probable future conditions (Searcy, 1959). Median-flow statistics in this report were determined using the Loaiciga (1989) approach.

## **Ungaged Stream Sites**

Estimates of streamflow statistics often are needed for sites on streams where no data are available. The two methods most commonly used to estimate statistics for ungaged sites are the drainage-area ratio method and multiple linear-regression analysis. The drainage-area ratio method is most appropriate for use when the ungaged site is near a streamflow-gaging station on the same stream. Multiple linear-regression analysis is used to obtain estimates for most other ungaged sites.

### **Drainage-Area Ratio Method**

The drainage-area ratio method assumes that the streamflow at an ungaged site for the same stream is the same per unit area or at least responds in the same fashion as that at a nearby, hydrologically similar streamflow-gaging station used as an index. Drainage areas for the ungaged site and the index station are determined from topographic maps, digital elevation maps (DEMs), or by other GIS methods. Streamflow statistics are computed for the index station, then the statistics are divided by the drainage area to determine

streamflows per unit area at the index station. These values are multiplied by the drainage area at the ungaged site to obtain estimated statistics for the site. This method is most commonly applied when the index gaging station is on the same stream as the ungaged site because the accuracy of the method depends on the proximity of the two sites and on similarities in drainage area and on other climatic and basin characteristics of the respective drainage basins.

Several researchers have provided guidelines as to how large the difference in drainage areas can be before use of multiple linear-regression analysis is preferred over use of the drainage-area ratio method. Guidelines have been provided for estimating peak-flow statistics, and usually the recommendation has been that the drainage area for the ungaged site should be within 0.5 and 1.5 times the drainage area of the index station (Choquette, 1988, p. 41; Koltun and Roberts, 1990, p. 6; Lumia, 1991, p. 34; Bisese, 1995, p. 13). One report (Koltun and Schwartz, 1986, p. 32) selected a range of 0.85 to 1.15 times the drainage area of the index station for estimating low flows at ungaged sites in Ohio. None of these researchers provided any scientific basis for use of these guidelines (R.E. Thompson, Jr., U.S. Geological Survey, written commun., 1999). In this report, the median flows at uncontrolled, ungaged locations are estimated by interpolation procedures using weighted drainage-area ratio from gaged sites and Tobit regression estimates at ungaged sites. No limit was placed on the ratios between the drainage area of the index station and the drainage area of the ungaged stream segment.

### **Multiple Linear-Regression Analyses**

Multiple linear-regression analysis (regression analysis) has been used by the USGS and other researchers throughout the United States and elsewhere to develop equations for estimating streamflow statistics at ungaged sites. In regression analysis, a streamflow statistic (the dependent variable) for a group of gaging stations is related statistically to the climatic or basin characteristics of the drainage basins for the stations (the independent variables). This results in an equation that can be used to estimate the statistic for sites where no streamflow data are available.

Equations can be developed by use of several different regression analysis algorithms. The various algorithms use different methods to minimize the differences between the values of the dependent variable for the stations used in the analysis (the observed

values) and the corresponding values provided by the resulting regression equation (the estimated or fitted values). Choice of one algorithm over another depends on the characteristics of the data used in the analysis and on the underlying assumptions for use of the algorithm. The multiple linear-regression equation takes the general form:

$$Y_i = b_0 + b_1X_1 + b_2X_2 + \dots + b_nX_n + \varepsilon_i \quad (1)$$

where  $Y_i$  is the value of the dependent variable for site  $i$ ,  $X_1$  to  $X_n$  are the  $n$  independent variables,  $b_0$  to  $b_n$  are the  $n + 1$  regression-model coefficients, and  $\varepsilon_i$  is the error (difference between the observed and estimated values of the dependent variable) for site  $i$ . Assumptions for use of regression analysis are (1) equation 1 adequately describes the relation between the dependent and the independent variables, (2) the variance of the  $\varepsilon_i$  is constant and independent of the values of  $X_n$ , (3) the  $\varepsilon_i$  are normally distributed for a Tobit regression, and (4) the  $\varepsilon_i$  are independent of each other (Inman and Conover, 1983, p. 367). Tobit regression is discussed in the following paragraph. Regression analysis results must be evaluated to assure that these assumptions are met. Streamflow and basin characteristics used in hydrologic regression usually are log normally distributed; therefore, transformation of the variables to logarithms is usually necessary to satisfy regression assumption 3. Transformation results in a model of the form:

$$\log Y_i = b_0 + b_1 \log X_1 + b_2 \log X_2 + \dots + b_n \log X_n + \varepsilon_i \quad (2)$$

The algebraically equivalent form when logarithms-base 10 ( $\log_{10}$ ) are used in the transformations, and the equation retransformed to original units is:

$$Y_i = 10^{b_0} (X_1^{b_1}) (X_2^{b_2}) \dots (X_n^{b_n}) 10^{\varepsilon_i}, \text{ or} \quad (3)$$

$$Y_i = 10^{[b_0 + b_1 \log X_1 + b_2 \log X_2 + \dots + b_n \log X_n + \varepsilon_i]}.$$

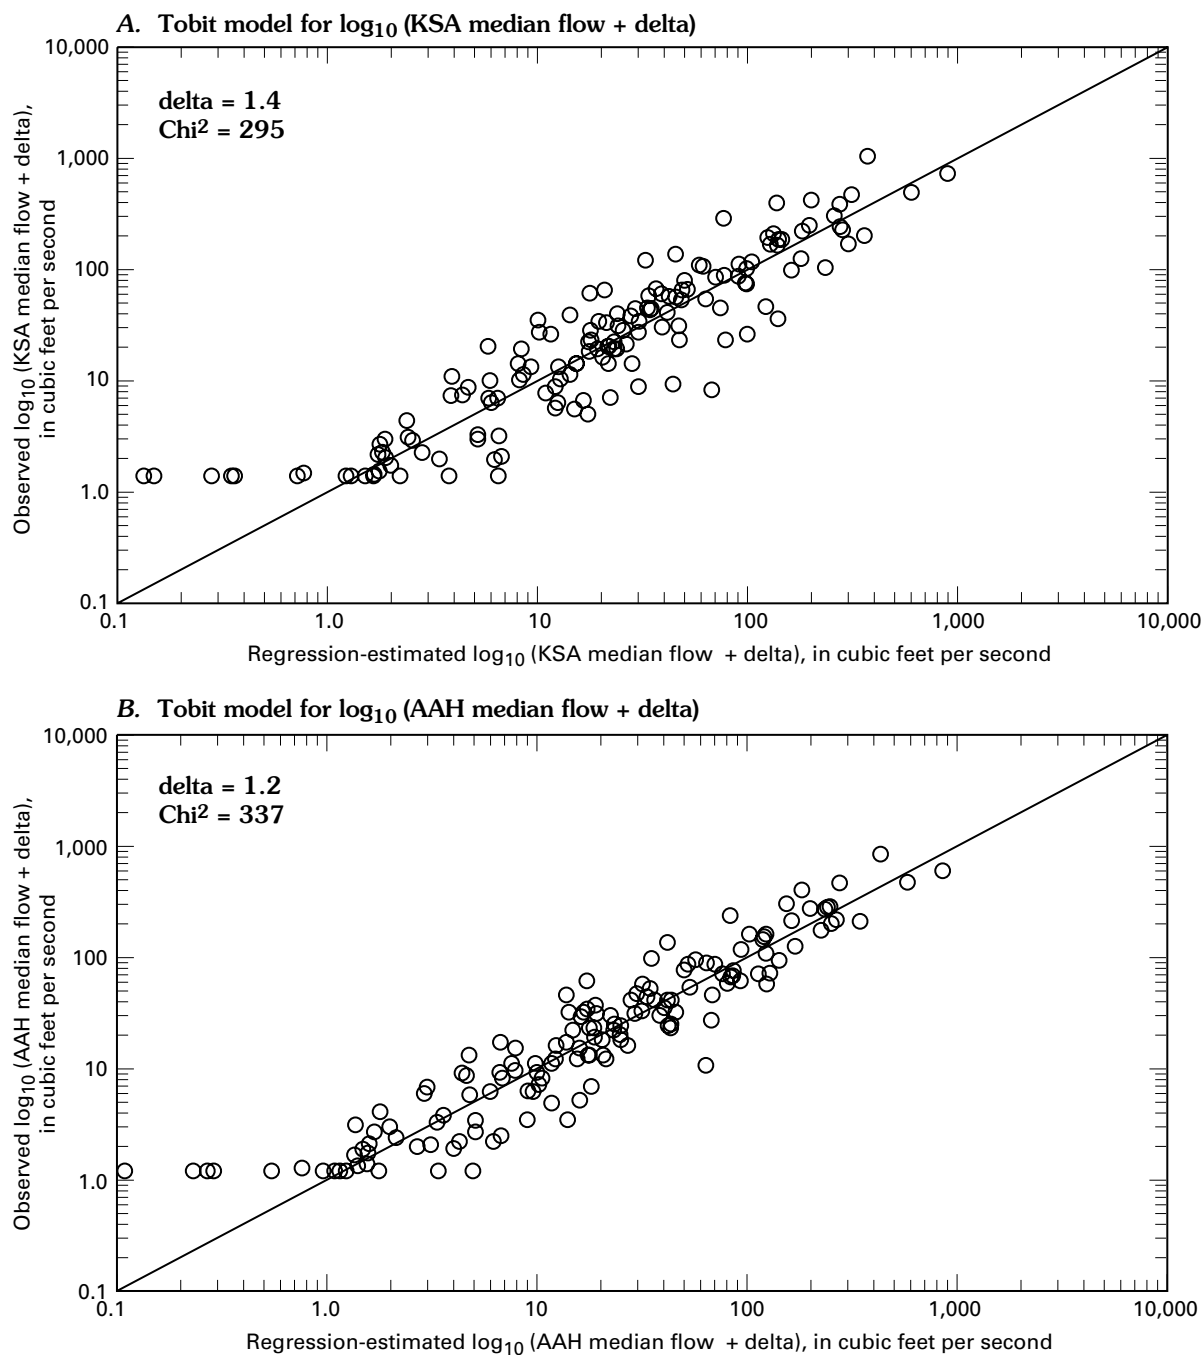

To include zero values in a logarithmic transformation regression analysis, the Tobit regression was used. Tobit regression is a widely accepted method for estimating a regression-like model when there are adjusted data (Tobin, 1958; Judge and others, 1985). Adjusted

data are data that are either censored or have had a discrete value delta ( $\delta$ ) added to them. Censored data are values below a threshold and are raised to the censoring value (for example, all values below 0.7 are raised to 0.7). Discrete values of delta ( $\delta$ ) are added to all data before transformation and then subtracted from the final regression model value. By applying these techniques, zero values of data can be transformed logarithmically. The Tobit procedure uses a maximum likelihood estimator. The Survival Regression Procedure in the S-Plus 2000 software package (MathSoft, 1999) was used in this study to fit the Tobit model.

A Tobit analysis was conducted on both the KSA and AAH data sets, and the resulting plots of observed versus regression-estimated values of median flow from the KSA and AAH data sets are shown in figures 6A and 6B. The graphs show the observed median flow plotted with the regression-estimated median flow. All observed and regression-estimated median flows have the delta value added. The  $\text{Chi}^2$  is a measure of the fit of the Tobit model. The delta value is varied until the  $\text{Chi}^2$  is maximized. The drainage area (DA) was divided by 1,000, the 30-year mean precipitation (PREC) was divided by 28, and the mean basin slope (SLOPE) was divided by 2 before the log transformation was made so that the log values were balanced between greater than and less than zero. This removed the multi-collinearity problems that occur when using squared values. The addition of the squares of log drainage area and log mean annual precipitation to the regression equation improved both KSA and AAH models substantially. The equations for regression-estimated median flow and uncertainty measures for KSA and AAH methods are listed in table 2. Only the 149 gages on uncontrolled streams with at least 10 years of record were used in the regression analyses. The drainage area of these gages ranged from 2.06 to 12,004  $\text{mi}^2$ .

KSA and AAH analyses provided regression estimates that were different. The KSA analysis used the most-recent 10 years of data. For many of the stations in this report this period was 1990 to 2000. However, more than 50 percent of the stations had their last data recorded before 1990 and more than 40 percent before 1980. Climate variability becomes a factor when 10 years of record from an earlier period is compared with a later period. Application of the KSA 82a–2001 criterion to use the most-recent 10 years of streamflow data may mean that a new analysis would be required every few years, and the resulting equation

**Figure 6.** Comparison of observed and regression-estimated median flows for (A) most-recent 10 years of record (KSA) and (B) all-available hydrology (AAH) using Tobit analysis.

always would reflect short-term (less than 10 years) climate variability.

The AAH analysis used all-available streamflow-data records that were from 10 to 90 years in length. Use of the entire period of record, which averaged 35 years for the 149 stations, incorporated all of the knowledge about streamflow at a particular site. The

climate of Kansas has gone through periods of wet and dry conditions, some of which have lasted longer than 10 years. The AAH analysis with its longer period of record incorporates long-term climate variability.

Although both sets of median flow data (KSA and AAH) have some nonoverlapping time periods, the analyses are still valid statistically. The different time

**Table 2.** Regression equations used to estimate median flows for uncontrolled stream segments on the Kansas Surface Water Register<sup>1</sup>

[Chi<sup>2</sup>, chi square statistical distribution; DA, drainage area in square miles; PREC, precipitation in inches; PERM, soil permeability in inches per hour; SLOPE, land-surface slope in degrees;

$$\log da = \log_{10}\left(\frac{DA}{1000}\right); \log prec = \log_{10}\left(\frac{PREC}{28}\right); \log perm = \log_{10} PERM; \log slope = \log_{10}\left(\frac{SLOPE}{2}\right)]$$

Flow value	Equation	Chi <sup>2</sup>	Standard error (log units)	Degrees of freedom
Median KSA (most-recent 10 years of record)	$Q_{KSA} = [10^{[1.74 + 1.088\log da + 4.867\log prec + 0.498\log perm + 0.513\log slope + 0.124(\log da)^2 - (16.154(\log prec)^2)]} - 1.4]$	295	0.285	143
Median AAH (entire period of record)	$Q_{AAH} = [10^{[1.689 + 1.127\log da + 5.298\log prec + 0.626\log perm + 0.515\log slope + 0.151(\log da)^2 + (-15.344(\log prec)^2)]} - 1.2]$	337	.247	143

<sup>1</sup>The Kansas Surface Water Register is maintained by the Kansas Department of Health and Environment (Topeka).

periods cover different streamflow regimes ranging from wet to dry. Had the most-recent 10 years been interpreted as the period 1991 to 2000, the analysis would have been biased toward trends or cyclicity in the climate during that period. By using the different time periods of streamflow data for AAH analysis, this bias is removed. The increased number of sampled days of flow in the AAH data set makes it more robust than the KSA data set, which has a reduced number of sampled days.

## **KANSAS SURFACE WATER REGISTER**

In 1994, the Kansas Department of Health and Environment (KDHE) adopted the Reach File Version 2 (RF2) stream-segment coverage within the State of Kansas as the basic coverage for stream classification. RF2 was completed in the late 1980s by the U.S. Environmental Protection Agency (USEPA) by using the Feature File of the USGS Geographic Names Information System (GNIS) to add one new level of reach segments to the Reach File Version 1 (RF1) coverage. The source of RF1 (completed in 1982) was the USGS's 1:250,000-scale hydrography that was photographically reduced to a scale of 1:500,000 by the National Oceanic and Atmospheric Association (NOAA). In addition to the RF2 segments, other segments have been added by KDHE to the Kansas Surface Water Register primarily for the protection of aquatic life and other water-quality issues. The original RF2 coverage has almost 30,000 subsegments in Kansas. By combining subsegments, the number of total segments for which median flows were determined in this report was reduced to 2,232, which equals the number of segments listed in the current (2002) Kansas Surface Water Register. This number is about 900 more segments than the RF1 coverage. The Kansas Surface Water Register of June 1, 1999, is a public document and can be obtained from the World Wide Web at <http://www.kdhe.state.ks.us/pdf/befs/register99.pdf>. In addition to the 2,232 classified segments, there are segments that are unregulated that include lakes, tribal streams, and irrigation ditches. These segments were included in this report to complete the stream drainage pattern for the State. Each segment on the Kansas Surface Water Register is identified by a unique CUSEGA number (Appendix C, table 6, at the end of this report). CUSEGA stands for catalog unit segment number alpha.

Because many of the stream basins in Kansas extend into the surrounding States, the data used for developing the Kansas Surface Water Register, which is based on the more detailed RF2, were joined with the national RF1 coverage that is available for Colorado, Missouri, Nebraska, and Oklahoma. This process was done by clipping the Kansas extent of the original RF1 stream coverage and replacing it with the more detailed version of the RF2 stream coverage. The two coverages were joined at the State boundaries for continuity. The line topology was reconfigured so that spatial relations between connecting stream segments (from and to nodes) were updated. Then the updated stream coverage was rechecked to correct any remaining digitizing errors including cycles, overshoots, and undershoots (that is, an arc that does not extend far enough to intersect another arc). Finally, the topology was checked for consistency (that is, all segments point downstream). All GIS analyses were performed using the Environmental Systems Research Institute (ESRI) ArcGIS and ArcInfo workstation.

A GIS database was used to manage and display the basin characteristics and estimated median flows for stream segments on the Kansas Surface Water Register. The relational database design facilitates identification and analysis of data unique to individual stream segments.

## **BASIN CHARACTERISTICS FOR STREAM SEGMENTS**

Drainage basins for each stream segment on the Kansas Surface Water Register were determined in the GIS by converting the vector stream-segment coverage into a raster-grid network with a raster size of 492 by 492 ft (150 by 150 m). Euclidean allocation was performed on the rasterized stream network to calculate for each cell the identity of the closest source or stream cell using the Euclidean distance. Euclidean distance is defined as the shortest length between two points in two-dimensional space.

Mean values for climatic and basin characteristics were calculated for stream-segment drainage basins using zonal statistics on basin-characteristic grids with Euclidean allocation zones. Zonal statistics were recorded in an attribute table and included the area and mean of the values of all cells in the basin-characteristic grids that belong to the same Euclidean zone. The climatic and basin characteristics computed included drainage area, mean annual precipitation, mean basin

elevation, mean basin permeability, mean basin slope, a Base Flow Index (BFI), and the Gebert and PRISM flow model values. Output zonal statistics tables were relationally joined back to the original vector streams coverage so that each reach had an estimated value for each climatic and basin characteristic.

## ESTIMATES OF MEDIAN FLOWS FOR STREAM SEGMENTS

Different procedures were used to estimate median flow for each stream segment on the Kansas Surface Water Register depending on whether the segment was controlled or uncontrolled and whether there was a streamflow-gaging station located either upstream or downstream from the segment. These interpolation procedures use the previously defined drainage-area ratio method and multiple linear-regression equations and are summarized in table 3. The interpolation procedures outlined in table 3 for an ungaged segment between two gaged segments selects the upstream gage segment (if there is more than one) that has the largest drainage area. These procedures were applied to flow statistics developed for KSA and AAH analyses for each stream segment on the Kansas Surface Water Register. Median-flow computations for controlled streamflow-gaging stations, used in the interpolation of the KSA and AAH analyses, are listed in table 4. Median-flow computations for the uncontrolled streamflow-gaging stations, used in the interpolation of the KSA and AAH analyses, are listed in table 5 (Appendix B). The AAH median flow at gages representing controlled stream segments (those with large reservoirs upstream) was computed from the controlled period of record only. These records had to be at least 10 years in length during the period 1960 to 2000. Use of the 1960 to 2000 time period maintains a degree of consistency for comparison and interpolation of median flows between gaging stations on controlled segments.

Figure 7 shows part of a stream network and some stream gages in central Kansas. The numbers next to the stream gages are the most-recent 10-year median flow values for those gages. Regression equations were developed in the section on "Multiple Linear-Regression Analyses." The numbers next to the stream segments are the median flow values estimated from those regression equations. A comparison of the stream-segment median flow values with the stream-gage median values shows substantial "local" differences between the stream-segment and stream-gage

values. Figure 8 shows the effect of using the local stream-gage median values to develop estimated median streamflow values by KSA analysis for the stream segments as outlined in table 3 and used in this report rather than only using the regression-estimated values. The local differences in estimated median flow values noted in figure 7 (regression estimates) are not as large in figure 8 (estimates derived in this report) because of the use of local stream-gage data. As a result, the interpolation procedure used in this report to develop median flow estimates appears to develop more accurate estimates than those that result from using only the regression equations.

The median flow information from streamflow-gaging stations and the regression equations from the KSA and the AAH analyses were used with the described interpolation procedures to generate a table of median flow values for the downstream end of stream segments on the Kansas Surface Water Register. The estimated median flow values for the KSA analysis and the AAH analysis are listed with their respective CUSEGA segment number in table 6 in Appendix C. In addition, three maps are provided on plates 1–3 in the back of this report. Plate 1 shows the location of USGS streamflow-gaging stations used in the interpolation procedure and Kansas Surface Water Register stream segments. Plate 2 shows estimated median flow values for each stream segment using the KSA analysis, and plate 3 shows estimated median flow values for each stream segment using the AAH analysis.

Of the 2,232 stream segments on the Kansas Surface Water Register, 30 percent of the segments had an estimated median flow of less than 1 ft<sup>3</sup>/s when the most-recent 10 years of data (KSA analysis) were used. When all-available data (AAH analysis) were used, which resulted in a regression equation with a lower level of uncertainty when compared to the KSA analysis, 40 percent of the stream segments had an estimated median flow of less than 1 ft<sup>3</sup>/s.

The uncertainty of the estimated median streamflows varies depending on the analysis used to determine the estimate for that segment. The greatest uncertainties exist for streams where no stream-gage information was available and only the regression estimates were used. For these segments, the uncertainty of the median flow estimate is the root mean square error of the regression estimate, which for the KSA analysis was 0.285 log units. This means that there is a 95-percent probability that the actual median flow for an estimate of 1 ft<sup>3</sup>/s is between 0.28 and 3.6 ft<sup>3</sup>/s

**Table 3.** Summary of interpolation procedures used to estimate median flow information for stream segments on the Kansas Surface Water Register (KSWR)

[Q, median flow; DA, drainage area; B, bias equals measured gaging station Q minus regression equation Q; Subscripts: r, regression-equation estimate of median flow; s, segment (ungaged); b, with bias added; u, upstream gaging station; d, downstream gaging station; g, at streamflow gage]

Case number	Case	Controlled segment interpolation procedure	Uncontrolled segment interpolation procedure
1	No gage on stream	Never occurs.	Use regression estimate (no adjustment).
2	Gage on that segment near <sup>1</sup> downstream end of segment	Use gaged value.	Use gaged value.
3	Gage on that segment not near <sup>1</sup> downstream end of segment	Estimate flow from gage data using ratio of gage drainage area to downstream end of KSWR segment drainage area. Ignore regression equations. $Q_s = \frac{Q_u}{DA_u} DA_s$	Use regression estimate adjusted by weighting the bias between the gaged value and the estimated value at the gaged site by the ratio of the gaged drainage area to the downstream end of the KSWR segment drainage area. $B_s = \frac{B_d}{DA_d} * DA_s$ $Q_{sb} = Q_{sr} + B_s$
4	Gage on stream only upstream or downstream of that segment	Estimate flow from gage data using ratio of gage drainage area to downstream end of KSWR segment drainage area. Ignore regression equations. $Q_s = \frac{Q_u}{DA_u} * DA_s \text{ or}$ $Q_s = \frac{Q_d}{DA_d} * DA_s$	Use regression estimate adjusted by weighting the bias between the gaged value and the estimated value at the gaged site by the ratio of the gaged drainage area to the downstream end of the KSWR segment drainage area. $B_s = \frac{B_u}{DA_u} * DA_s$ $Q_{sb} = Q_{sr} + B_s$
5	Gage on stream both upstream and downstream of that segment	Estimate the flow from upstream and downstream gage data using weighted average ratios of gage drainage areas to downstream end of KSWR segment drainage area. Ignore regression equations. $Q_s = \frac{Q_u(DA_d - DA_s) + Q_d(DA_s - DA_u)}{DA_d - DA_u}$	Use regression estimate adjusted by a weighted average bias between the two gages. $B_s = \frac{B_u(DA_d - DA_s) + B_d(DA_s - DA_u)}{DA_d - DA_u}$ $Q_{sb} = Q_{sr} + B_s$

<sup>1</sup>Near is defined as location on the stream segment that is downstream from any natural hydrologic break, such as a tributary stream.

<sup>1</sup>The Kansas Surface Water Register is maintained by the Kansas Department of Health and Environment (Topeka).

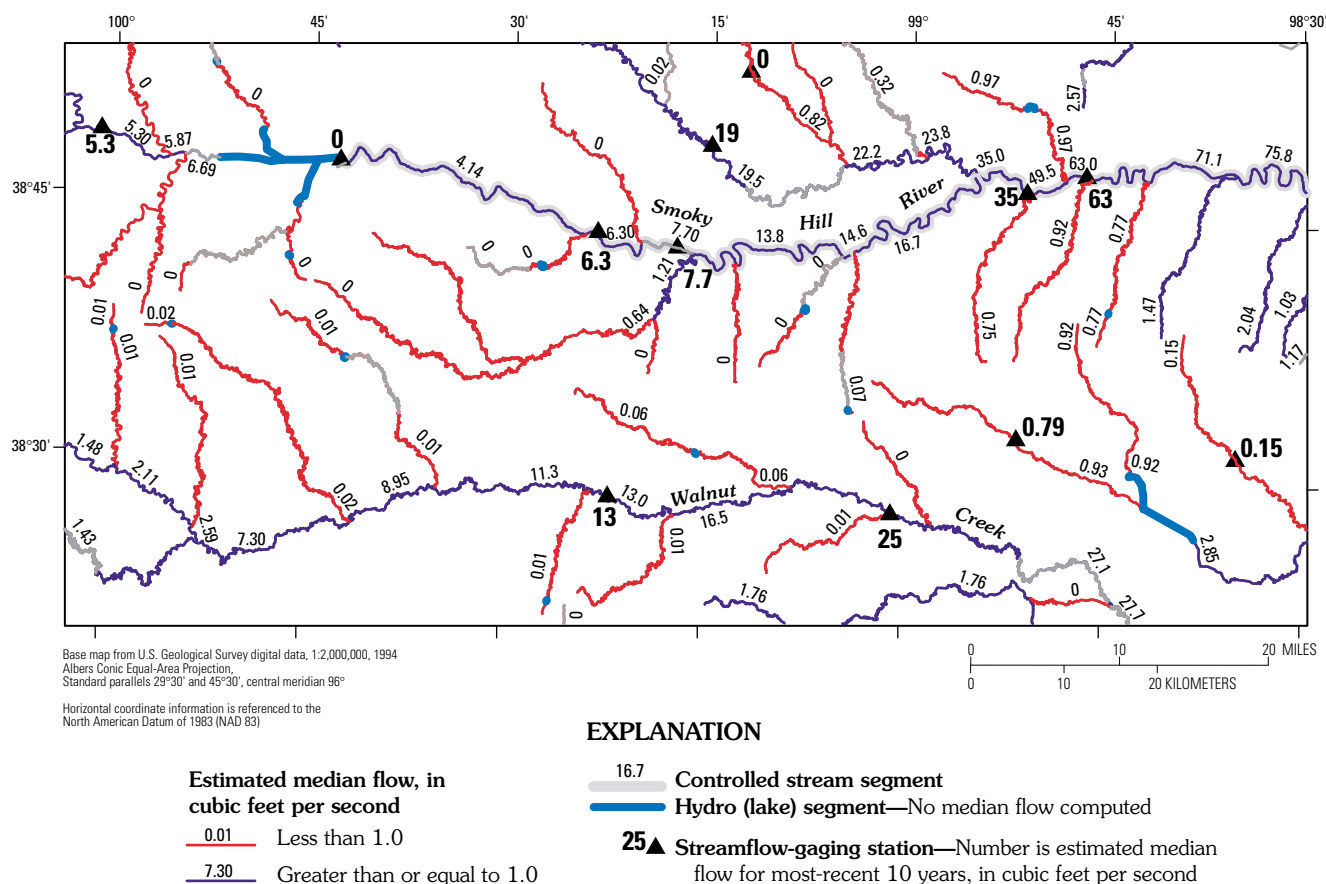

Note: Numbers next to the stream segments are median flow values estimated from regression equations. Estimated median flow values do not match those on plate 2.

**Figure 7.** Median flow values for stream segments in central Kansas estimated from regression equations and observed streamflow-gaging-station data for the most-recent 10 years of record (KSA) analysis.

(72 to 260 percent). For the AAH analysis, the root mean square error was 0.247 log units (table 2), which translates into a 95-percent probability that the actual median flow for an estimate of 1 ft<sup>3</sup>/s is between 0.33 and 3.04 ft<sup>3</sup>/s (67 to 204 percent). The lowest uncertainties exist for stream segments with gages near the downstream end of those segments. For these stream segments the uncertainty is a fraction of the uncertainty of the gaging-station flow measurement and rating process due to the central tendency of the median statistic. The average uncertainty for those segments with gages varies from 7.3 percent for the KSA data to 4.3 percent for the AAH data. The 95-percent confidence intervals for the gaged data used in the interpolation are listed in table 5 in Appendix B. Reporting estimated median values in table 6 and on plates 2 and 3 to three significant figures was done to conform with the intent of KSA 82a–2001 et. seq. and does not denote the level of accuracy of the estimates.

## INTERNET DISSEMINATION OF RESULTS

This report and its associated figures, tables, appendices, plates, and the GIS database are available and can be downloaded from the World Wide Web at <http://ks.water.usgs.gov/Kansas/strmstats>. This web page is maintained by the USGS and has links to the GIS database described in this report in order to display the information on median flow by county for the State of Kansas. Estimated median flows from the KSA and AAH analyses are available for stream segments on the Kansas Surface Water Register. The county-map format includes county boundaries, State and Federal highways, and the stream segments for spatial reference. The estimated median flow values using the KSA and AAH analyses, indexed with their respective segment identifier number, are displayed as a pop-up window as the cursor is placed over a stream segment.

**Figure 8.** Estimated median flow values for stream segments in central Kansas using interpolation procedures outlined in table 3 and observed streamflow-gaging-station data for the most-recent 10 years of record (KSA) analysis.

## SUMMARY

The Kansas State Legislature, by enacting Kansas Statute 82a–2001 et. seq. (KSA), has mandated the selection of Kansas streams for water-quality classification by the State. One criterion for selecting stream segments for classification is whether stream segments listed on the Kansas Surface Water Register have a median flow equal to or greater than 1 ft<sup>3</sup>/s. Therefore, information on median flow characteristics is needed for streams in Kansas. Daily streamflow information available for 214 gaging stations within Kansas and in adjacent States were used by the USGS in cooperation with KDHE to compute these statistics at gaged sites and to estimate these statistics at ungaged sites.

Least-squares multiple-regression techniques, along with Tobit analyses, were used to develop equations for estimating median flow (dependent variable) for ungaged, uncontrolled stream segments. Median flows were determined from streamflow-gaging station data using the most-recent 10 years of gaged data as

defined by KSA analysis, and from the entire period of record, which is defined in this report as the all-available hydrology (AAH) analysis. Independent variables in the regression equations were the climatic and basin characteristics for streams flowing through Kansas. In the development of the regression equations, the significant climatic and basin characteristics, in order of importance, were drainage area, mean annual precipitation, mean basin permeability, and mean basin slope. Only the 149 gages on uncontrolled streams with at least 10 years of streamflow record were used in the regression analyses. The drainage area of these gages ranged from 2.06 to 12,004 mi<sup>2</sup>.

A logarithmic transformation of the basin characteristics was needed to develop a linear relation for computing median flows. Because there were numerous zero values for median gaging-station flows, the Tobit regression was used to include those zero values in the regression. The resulting regression equations

and an interpolation procedure were used to estimate median flows for the uncontrolled stream segments on the Kansas Surface Water Register.

Streamflow-gaging-station data were used to improve the quality of the estimates along the streams that had gages. Median flows for the segments that were uncontrolled were interpolated using gaged data weighted according to the drainage area and the bias between the regression estimate and gaged flow information. On controlled reaches of Kansas streams, the median flow information was interpolated between gaging stations by using only gaged data weighted by drainage area.

Of the 2,232 stream segments on the Kansas Surface Water Register, 30 percent of the segments had an estimated median flow of less than 1 ft<sup>3</sup>/s when the most-recent 10 years of data (KSA analysis) were used. When all-available data (AAH analysis) were used, which resulted in a regression equation with a lower level of uncertainty when compared to KSA analysis, 40 percent of the stream segments had an estimated median flow of less than 1 ft<sup>3</sup>/s.

**APPENDIX A.—KANSAS STATUTE KSA 82a–2001 et. seq.**

**Kansas Statute No. 82a-2001**  
**Chapter 82a.--WATERS AND WATERCOURSES**  
**Article 20.--CLASSIFIED STREAM SEGMENTS**

**82a-2001. Classified stream segments defined; other definitions.** As used in this act:

(a) (1) "Classified stream segments" shall include all stream segments that are waters of the state as defined in subsection (a) of K.S.A. 65-161, and amendments thereto, and waters described in subsection (d) of K.S.A. 65-171d, and amendments thereto, that:

(A) Are indicated on the federal environmental protection agency's reach file 1 (RF1) (1982) and have the most recent 10-year median flow of equal to or in excess of 1 cubic foot per second based on data collected and evaluated by the United States geological survey or in the absence of stream segment flow data, calculations of flow conducted by extrapolation methods provided by the United States Geological Survey;

(B) have the most recent 10-year median flow of equal to or in excess of 1 cubic foot per second based on data collected and evaluated by the United States geological survey or in the absence of stream segment flow data, calculations of flow conducted by extrapolation methods provided by the United States geological survey;

(C) are actually inhabited by threatened or endangered aquatic species listed in rules and regulations promulgated by the Kansas department of wildlife and parks or the United States fish and wildlife service;

(D) (i) scientific studies conducted by the department show that pooling of water during periods of zero flow provides important refuges for aquatic life and permits biological recolonization of intermittently flowing segments; and

(ii) a cost/benefit analysis conducted by the department and taking into account the economic and social impact of classifying the stream segment indicates that the benefits of classifying the stream segment outweigh the costs of classifying the stream segment, as consistent with the federal clean water act and federal regulations; or

(E) are at the point of discharge on the stream segment and downstream from such point where the department has issued a national pollutant discharge elimination system permit other than a permit for a confined feeding facility, as defined in K.S.A. 65-171d, and amendments thereto.

(2) Classified stream segments other than those described in subsection (a)(1)(E) shall not include ephemeral streams; grass, vegetative or other waterways; culverts; or ditches.

(3) Any definition of classified stream or "classified stream segment" in rules and regulations or law that is inconsistent with this definition is hereby declared null and void.

(b) "Department" means the department of health and environment.

(c) "Designated uses of classified stream segments" shall be defined as follows:

(1) "Agricultural water supply use" means the use of a classified stream segment for agricultural purposes, including the following:

(A) "Irrigation" means the withdrawal of water from a classified stream segment for application onto land; or

(B) "livestock watering" means the provision of water from a classified stream segment to livestock for consumption.

(2) "Aquatic life support use" means the use of a classified stream segment for the maintenance of the ecological integrity of streams, lakes and wetlands, including the sustained growth and propagation of native aquatic life; naturalized, important, recreational aquatic life; and indigenous or migratory semi aquatic or terrestrial wildlife directly or indirectly dependent on surface water for survival. Categories of aquatic life support use include:

(A) "Special aquatic life use waters" means classified stream segments that contain combinations of habitat types and indigenous biota not found commonly in the state, or classified stream segments that contain representative populations of threatened or endangered species, that are listed in rules and regulations promulgated by the Kansas department of wildlife and parks or the United States fish and wildlife service.

(B) "Expected aquatic life use waters" means classified stream segments containing habitat types and indigenous biota commonly found or expected in the state.

(C) "Restricted aquatic life use waters" means classified stream segments containing indigenous biota limited in abundance or diversity by the physical quality or availability of habitat, due to natural deficiencies or artificial modifications, compared to more suitable habitats in adjacent waters.

(3) "Domestic water supply" means the use of a classified stream segment, after appropriate treatment, for the production of potable water.

(4) "Food procurement use" means the use of a classified stream segment for the obtaining of edible forms of aquatic or semi aquatic life for human consumption.

(5) "Groundwater recharge use" means the use of a classified stream segment for the replenishing of fresh or usable groundwater resources. This use may involve the infiltration and percolation of surface water through sediments and soils or the direct injection of surface water into underground aquifers.

(6) "Industrial water supply use" means the use of a classified stream segment for nonpotable purposes by industry, including withdrawals for cooling or process water.

(7) (A) "Recreational use" means:

(i) Primary contact recreational use is use of a classified stream segment for recreation during the period from April 1 through October 31 of each year, provided such classified stream segment (a) by law or written permission of the landowner is open to and accessible by the public and (b) is capable of supporting the recreational activities of swimming, skin diving, water-skiing, wind surfing, boating or mussel harvesting where the body is intended to be immersed in surface water to the extent that some inadvertent ingestion of water is probable;

(ii) Secondary contact recreational use:

(a) is use of a classified stream segment for recreation, provided such classified stream segment (1) by law or by written permission of the landowner is open to and accessible by the public and (2) is capable of supporting the recreational activities of wading or fishing where the body is not intended to be immersed and where ingestion of surface water is not probable; or

(b) is use of a classified stream segment for recreation, provided such classified stream segment (1) is not open to and accessible by the public under Kansas law and (2) is capable of supporting the recreational activities of swimming, skin diving, water-skiing, wind surfing, boating, mussel harvesting, wading or fishing.

(B) If opposite sides of a classified stream segment would have different designated recreational uses due to differences in public access, the designated use of the entire classified stream segment may be the higher attainable use, notwithstanding that such designation does not grant the public access to both sides of such segment.

(C) Recreational use designations shall not apply to stream segments where the natural, ephemeral, intermittent or low flow conditions or water levels prevent recreational activities.

(d) "Ephemeral stream" means streams that flow only in response to precipitation and whose channel is at all times above the water table.

(e) "Secretary" means the secretary of health and environment.

**History:** L. 2001, ch. 100, § 1; Sept. 1

**Kansas Statute No. 82a-2002**  
**Chapter 82a.--WATERS AND WATERCOURSES**  
**Article 20.--CLASSIFIED STREAM SEGMENTS**

**82a-2002. Establishment of classified stream segments; use of such.** Notwithstanding any other provisions of law and in addition to the powers of the secretary pursuant to K.S.A. 65-171d, and amendments thereto, the secretary shall establish classified stream segments in Kansas and, following such classification, designate use of such classified stream segments pursuant to K.S.A. 2001 Supp. 82a-2003 and 82a-2004, and amendments thereto.

**History:** L. 2001, ch. 100, § 2; Sept. 1.

**Kansas Statute No. 82a-2003**  
**Chapter 82a.--WATERS AND WATERCOURSES**  
**Article 20.--CLASSIFIED STREAM SEGMENTS**

**82a-2003. Determination of which stream segments are listed as classified stream segments; duration of determination.** (a) Prior to December 31, 2002, the department shall review all stream segments listed on the 1999 Kansas surface water register and determine whether such stream segments meet the definitions of classified stream segments pursuant to paragraph (a)(1)(A) or (a)(1)(B) of K.S.A. 2001 Supp. 82a-2001, and amendments thereto. The department shall begin the review with stream segments listed on the 1999 Kansas surface water register west of the 98th longitude line and consider stream flow data or methodologies of extrapolating flow from the United States geological survey.

(b) Prior to December 31, 2005, the department shall review all stream segments listed on the 1999 Kansas surface water register which do not meet the definitions of classified stream segments pursuant to paragraph (a)(1)(A) or (a)(1)(B) of K.S.A. 2001 Supp. 82a-2001, and amendments thereto, and determine whether such stream segments meet the definitions of classified stream segments pursuant to paragraph (a)(1)(C), (a)(1)(D) or (a)(1)(E) of K.S.A. 2001 Supp. 82a-2001, and amendments thereto. The department shall establish a procedure, adopted in rules and regulations, requiring that all of the reviews and findings have been met pursuant to paragraph (a)(1)(D) of K.S.A. 2001 Supp. 82a-2001, and amendments thereto.

(c) All current stream classifications shall remain in effect until December 31, 2005, or as deleted or changed through the procedures set forth above.

**History:** L. 2001, ch. 100, § 3; Sept. 1.

**Kansas Statute No. 82a-2004**  
**Chapter 82a.--WATERS AND WATERCOURSES**  
**Article 20.--CLASSIFIED STREAM SEGMENTS**

**82a-2004. Listing of all currently classified stream segments; minimum action for unclassified stream segments; information available to public; duration of designation.** (a) Prior to October 15, 2001, the department shall make publicly available a listing of all currently classified stream segments for which: (1) Designated use attainability analyses for recreational use have been completed; (2) recreational use has been determined not attainable; or (3) designated use attainability analyses for recreational use have not been completed. For such classified stream segments for which designated use attainability analyses for recreational use have not been completed, the department, at a minimum, shall complete a designated use attainability analysis for recreational use according to the following schedule:

(A) An aggregate of at least 25% of such classified stream segments shall have a designated use attainability analyses for recreational use completed prior to October 31, 2002.

(B) An aggregate of at least 50% of such classified stream segments shall have a designated use attainability analyses for recreational use completed prior to October 31, 2003.

(C) An aggregate of at least 75% of such classified stream segments shall have a designated use attainability analyses for recreational use completed prior to October 31, 2004.

(D) All of such classified stream segments shall have designated use attainability analyses for recreational use completed prior to October 31, 2005.

(b) Prior to October 15, 2002, the department shall make publicly available a listing of all currently classified stream segments for which: (1) Designated use attainability analyses for use other than recreational use have been completed; (2) use other than recreational use has been determined not attainable; or (3) designated use attainability analyses for use other than recreational use have not been completed. For such classified stream segments for which designated use attainability analyses for use other than recreational use have not been completed, the department, at a minimum, shall complete a designated use attainability analysis for use other than recreational use according to a schedule adopted before June 1, 2004, by rules and regulations of the secretary.

(c) Barring flooding or acts of God, which would prevent the department from completing designated use attainability analyses, the schedules provided for pursuant to subsections (a) and (b) shall be accelerated to allow for completion of designated use attainability analyses for all designated uses on or before December 31, 2007.

(d) All current designated uses of classified stream segments listed on the Kansas surface water register 1999 shall remain in effect until December 31, 2007, or until deleted or changed through the procedures set forth above.

**History:** L. 2001, ch. 100, § 4; Sept. 1.

**Kansas Statute No. 82a-2005**  
**Chapter 82a.--WATERS AND WATERCOURSES**  
**Article 20.--CLASSIFIED STREAM SEGMENTS**

**82a-2005. Publication of attainability analysis protocols; review of use attainability analysis; updating of Kansas surface water register.** (a) Prior to December 1, 2001, the secretary shall publish as guidance designated use attainability analysis protocols for the revision and adoption of designated uses of classified stream segments to protect the public health or welfare and to enhance the quality of classified stream segments. The secretary shall take into consideration the uses and values of such waters for public water supplies, propagation of fish and wildlife, navigation and recreational, agricultural, industrial and other purposes.

(b) The designated use attainability analysis protocols shall include, if applicable for the respective designated use, procedures for:

(1) Review of physical, chemical, biological and economic and social factors affecting attainment of a use or uses;

(2) review of naturally-occurring pollutant concentrations and conditions affecting attainment of a use or uses;

(3) review of natural, ephemeral, intermittent or low flow conditions or water levels affecting attainment of a use or uses;

(4) review of human conditions that prevent attainment of a use or uses, including state laws, and that cannot be remedied or that would cause more damage or an inproportionate cost to remedy than to leave in place;

(5) review of hydrologic modifications such as dams and diversions affecting attainment of a use or uses;

(6) review of physical conditions related to natural features such as lack of proper substrate, cover, flow, depth, pools, riffles and other stream morphology affecting attainment of a use or uses;

(7) identification and description of cost-effective and reasonable best management practices for non-point source pollutant control where such control would be needed to attain a use or uses; and

(8) qualified persons outside the department to conduct designated use attainability analyses.

(c) A use or uses shall not be designated unless it is demonstrated that such use or uses are actually existing and attainable, or unless it is demonstrated that the adverse social and economic impacts of designating a use or uses that are not actually existing are outweighed by the social and economic benefits resulting from the attainment of such use or uses.

(d) Within 60 days after receipt of submission of a use attainability analysis, the department shall review and provide a written determination of whether the documentation submitted is complete.

(e) Within 60 days after receipt of submission of a complete use attainability analysis, the department shall review and provide a written determination of whether revision of the designated use will be proposed as a rule and regulation. Any person aggrieved by such determination may make written request, within 30 days after receipt of such determination, for a meeting with the secretary or the secretary's designee to discuss the determination and exchange information.

(f) All proposed revisions to the surface water register shall be proposed for adoption in accordance with the rules and regulations filing act (K.S.A. 77-415, and amendments thereto).

(g) Following the promulgation of a revision of the surface water register as a rule and regulation pursuant to subsections (d) and (e), any person aggrieved by such promulgation, within 15 days after publication of the rule and regulation, may request a hearing by filing an application for an order under the Kansas administrative procedure act. Any action of the secretary in a proceeding pursuant to this subsection is subject to review in accordance with the act for judicial review and civil enforcement of agency actions.

(h) The Kansas surface water register shall be updated and published annually.

**History:** L. 2001, ch. 100, § 5; Sept. 1.

**Kansas Statute No. 82a-2006**  
**Chapter 82a.--WATERS AND WATERCOURSES**  
**Article 20.--CLASSIFIED STREAM SEGMENTS**

**82a-2006. Reports to the governor and legislature.** (a) Annually, on or before the first day of the legislative session, the secretary shall prepare and submit a report to the governor and the chairperson, vice-chairperson and ranking minority member of the standing committees of the house of representatives and the senate on environment and natural resources regarding the status of completing the classification of streams as required in K.S.A. 2001 Supp. 82a-2003, and amendments thereto, and designated use attainability analyses as required in K.S.A. 2001 Supp. 82a-2004, and amendments thereto.

(b) On or before February 15, 2003, the secretary shall report to the governor and the chairperson, vice-chairperson and ranking minority member of the standing committees of the house of representatives and the senate on environment and natural resources regarding the status of new methodologies of measuring stream flow, in particular that under development by the United States geological survey.

**APPENDIX C.—ESTIMATED MEDIAN FLOWS AT DOWNSTREAM END OF STREAM SEGMENTS ON THE  
KANSAS SURFACE WATER REGISTER**

**Table 6. Stream segments on the Kansas Surface Water Register, CUSEGA numbers, stream names, and estimated median flows at downstream end of CUSEGA segments using the most-recent 10 years of record (KSA) and all-available hydrology (AAH) analyses**

[Estimated median flows are rounded to three significant figures; ft<sup>3</sup>/s, cubic feet per second. Reporting estimated median values to three significant figures (median greater than or equal to 1 ft<sup>3</sup>/s) or two significant figures (median less than 1 ft<sup>3</sup>/s) was done to better conform with the intent of KSA 82a-2001 et. seq. Shaded areas show corrections to original printed report.]

Stream segment number (plate 1)	CUSEGA number	Stream name	Estimated median flows (ft <sup>3</sup> /s)
