RECORDS OF WELLS ON THE SNAKE RIVER PLAIN, IN SOUTHEASTERN IDAHO

By Harold T. Stearns, Lynn Crandall, and Willard G. Steward

INTRODUCTION

The well records that are given in this volume were obtained in connection with an investigation of the ground-water resources of the Snake River Plain, in southeastern Idaho. The investigation was begun by the United States Geological Survey May 1, 1928. It was conducted in cooperation with the Idaho Bureau of Mines and Geology and the Idaho Department of Reclamation. The North Side Canal Co., the Twin Falls Canal Co., the Minidoka and Burley irrigation districts, and the Idaho Power Co. cooperated through the Idaho Department of Reclamation.

The general report on this investigation will be published as Water-Supply Paper 774, to which this report is a factual supplement. The map showing the contours of the water table, appearing as a plate in Water-Supply Paper 774, was released in manuscript form for public use on September 5, 1930, and the well records appearing herein were similarly released on August 7, 1931.

The main purpose of the investigation was to determine as far as possible the direction of movement of the ground water in the Snake River Plain above King Hill and the respective amounts of water contributed to the great underground reservoir by seepage from the Snake River and tributary streams, by precipitation on the plains themselves, and by irrigation water that percolates below the root zone. Efforts were also made to determine where the water lost from certain stretches of the Snake River returns again to the river and the time interval involved in the transmission of this water underground. The geology of the region was studied for the light that it might throw on the occurrence of the ground water and the geologic structure that affects its movement. To determine the direction in which the ground water is moving in different parts of the region, the position of the water table (or upper surface of the body of ground water) was determined by measuring the depth to the water level in as many wells as possible and by connecting the reference points at the wells with a network of levels. From these data the maps were prepared that show the contours of the water table and the depth to the water table. All records of wells obtained in the past by reliable organizations were assembled and studied to determine the changes in the water levels in the wells as a result of differences in precipitation and irrigation development. The results of these studies are presented in Water-Supply Paper 774.

In the investigation of ground-water levels at least one well was recorded for each square mile in areas where wells were numerous, so as to have them evenly distributed. In outlying districts, especially in the desert part of the plain, where wells were few or where unusual ground-water conditions were anticipated, all wells where the depth to the water level could be ascertained by report or measurement were recorded. Considerable ingenuity was required to measure many of the deep wells covered with heavy pump heads. All measurements were made with steel tapes from definite points to which levels were later run. A heavy tripod with block and tackle was at first used to lift the pumps so that the depth to the water level in the wells could be measured. Later steel drills were used, and the men became very adept at drilling the casing or pump head, threading the hole, measuring the depth to the water level, and inserting a plug after the measurement was made. Except where drip or some other difficulty was encountered a well was tapped, measured, and plugged in 15 minutes. Mr. Steward rigged up an efficient reel for winding up the 500-foot tape. Some of the tapes were purposely allowed to rust or were coated with a special brown paint to show a good water line when immersed. No weights were added to the ends of the tapes in measuring the deep wells because they caught too easily on obstructions. Whenever any doubt existed as to the accuracy of the measurements, the well was remeasured before the results were recorded in the notes. The greatest difficulty encountered in measuring wells was caused by water dripping from some higher level into them. Most of them are not cased, and hence water from nearby irrigated fields, troughs, or leaky pumps readily runs into the wells. In some of the wells there was so much drip during the first visit that it was necessary to make a second and even a third visit to obtain a reliable measurement.

On most of the wells a copper washer bearing the letters "U.S.G.S.W.R." was set with a 2-inch copper nail. At some wells the head of the nail serves as a bench mark; at others it serves as the reference point from which the depth to the water level was measured. It was recognized that for most of the deep wells the top of the casing is the most permanent measuring point, but the copper washer served to identify the well for the engineers who leveled to both the top of the casing and to the bench.

In the interest of speed and accuracy, some of the level lines were not closed, and many were started from the top of a railroad rail, the middle line of a highway, or some canal structure where the altitude had previously been established within a few inches by some other agency. An effort was made to have the altitude of the measuring point determined within a few

tenths of a foot of its exact altitude, although slight errors in the initial altitude may have caused some of them to be as much as a foot in error. Because of the regularity of the water table, errors as great as a foot could in most places in the plain be detected when the water-table contours were plotted. The water-table map was completed in 1929, hence general discrepancies were discovered before the end of the field work, and consequently the wells could be revisited if necessary. In most parts of the plain the water levels in the wells, both shallow and deep, are nearly at the level of the water table. Hence, for most areas shallow and deep wells have been used indiscriminately in the preparation of the water-table map. Artesian pressure is probably the cause of the domes in the water table at Fort Hall and near Kimama. A few areas of perched water occur, the largest of which are in the vicinity of Market Lake and Mud Lake.

All maps, field notes, and other data in possession of the several cooperating parties were made available for use in this investigation. Before a contour map of the water table in the region under investigation could be constructed, a base map showing townships and sections had to be compiled. In addition to the available maps of the United States Geological Survey, valuable maps were supplied by the United States Forest Service, the United States Bureau of Reclamation, the United States Bureau of Indian Affairs, the Twin Falls Canal Co., the Minidoka Irrigation Co., the Oregon Short Line Railway, the Idaho State Bureau of Highways, and the Salmon River Canal Co. County maps were also used insofar as such maps were available. For the parts of the area not covered by other maps the township plats of the United States General Land Office were used. The altitudes of all the measuring points of the wells given in this report are referred to the sea level datum established by the United States Coast and Geodetic Survey.

Well records in the area between Ashton and Rexburg were collected in 1928 by W. G. Steward, J. H. Boone, and L. H. Perrine, of the Twin Falls Canal Co. The part of the contour map of the water table covering the Mud Lake area is based on information obtained in 1921 and 1922 by Mr. Stearns, supplemented by measurements made in 1929 by Mr. Steward. In the area between Boise and Menan levels were run to many wells, under the direction of G. C. Baldwin, by members of the United States Geological Survey who also made measurements of the depths to the water levels. These wells were measured in 1923 to 1927, and the results appear in the table of well records. The water-table map of this area is, however, largely based on measurements made by Mr. Boone in September and October 1928 and on levels run by Mr. Perrine, who also measured some wells.

The water-table map in the area between Idaho Falls and Blackfoot is largely based upon measurements made in September and October 1928 by H. G. Haight, of the Twin Falls Canal Co. The wells in this area that were measured in 1920 by Fred Schlapkohl, of the United States Bureau of Reclamation, and in 1926 by L. T. Burdick, of the North Side Canal Co., are also shown on the map, and the records are given in the table.

Most of the records for wells on the Fort Hall project and the Michaud Flats area were obtained by Mr. Haight. Additional data included in the table of well records were obtained by Mr. Schlapkohl in April 1919, by Mr. Burdick in 1926, and by W. B. Heroy,[1] of the United States Geological Survey, in 1914. The water-table map of this area was constructed by using the measurements made by Mr. Haight in September and October 1928.

Records of wells on the Aberdeen-Springfield tract were furnished by the United States Bureau of Reclamation, and T. R. Newell, while working in this area, recorded additional measurements which are included. The water-table contours for this area as shown on the map represent the position in September 1928.

The wells in the area between American Falls and Declo, which includes the Rockland and Raft River Valleys and the Albion territory, were chiefly located and leveled by Mr. Perrine in 1928. Messrs. Steward and Stearns measured and recorded many of the wells in the Raft River Valley.

The records of wells in the Minidoka South Side project were supplied by the United States Bureau of Reclamation. The water-table map for this project was drawn on the basis of the well measurements made in September 1928.

The records of wells on the Minidoka North Side tract were furnished by the Minidoka Irrigation District and Mr. Steward. Mr. Steward's measurements were made in September 1927 and were used to draw the water-table map of this tract. Well measurements were made from 1910 to 1928 on this project and are on file in the office of the Minidoka Irrigation District in Rupert and at the office of the United States Bureau of Reclamation in Burley. Because of the small amount of change in the water table it was not deemed advisable to publish all the measurements for the above-mentioned years, and therefore only the records for 1911, 1920, 1927, and 1928 appear in the table.

---

1 Heroy, W. B., Water resources of the Fort Hall Indian Reservation, Idaho: U. S. Geol. Survey Bull. 713, p. 135, 1920.

Part of the well records for the Twin Falls North Side project were furnished by the North Side Canal Co., but additional wells were measured in 1929 by John McDonnell and Mr. Steward, and these were used to draw the map of the water table of this project.

Most of the well records for the Twin Falls South Side project were obtained from the Twin Falls Canal Co. In 1914 Mr. Heroy made an investigation of the geologic and ground-water conditions in this area, and the wells measured by him are included in the table. The water-table map for this project was drawn by using the well measurements made during September and October 1928.

The location of wells and the measurements of depth to water in the Soda Springs area were made chiefly in 1923 by Mr. Stearns in connection with an investigation of reservoir sites, but additional measurements were made in October 1927 and September 1928 by Mr. Haight. The map of the water table in this area was based on the measurements made in 1923, 1927, and 1928. The altitudes of the measuring points of the wells in this area are referred to sea-level datum. Levels were run to the wells by Myron Swendsen, engineer of the Empire Irrigation District, and by Mr. Haight.

The location and the measurements of depth to water of the wells in Portneuf River and March Valley areas were made in August and September 1928, by Mr. Haight, who also ran levels to the wells at the same time. The map of the water table in these areas was based entirely upon these records.

The location and measurements of depth to water of the wells in the sparsely settled desert area were made by Messrs. Perrine, Haight, Steward, Boone, and Stearns, who also ran the levels to these wells.

TABLE OF WELL RECORDS

This table gives information about the location, ownership, type, and depth of the wells in which measurements of the depth to the water level were made. It also gives the altitude and description of the measuring points from which the depths to the water level were measured. The location is given by section and subdivision thereof. Thus the location of the first well recorded is given as "NW-SW 29," indicating that the well is in the NW¼SW¼ sec. 29. The altitude is given in feet and tenths of a foot above sea level, determined as indicated in the introduction. An asterisk (*) indicates that the altitude was determined with an aneroid barometer; otherwise it was generally determined by leveling. In the descriptions of the measuring points the term "surface" is used to denote the natural surface of the land at the well. The records of depths to the water levels are given in the table of water-level measurements, pages 59 to 139.

TABLE OF WATER-LEVEL MEASUREMENTS

The first column gives the location of the wells that were measured and corresponds to the first column in the preceding table of well records, which gives additional information in regard to each well. Thus on page 6 it is shown that the first well recorded is in the NW¼SW¼ sec. 29, T. 1 N., R. 19 E., is owned by C. H. Shaw, and is 87 feet deep, and that the point from which the measurement of depth to the water level was made is 5,002.2 feet above sea level and about at the level of the land surface.

The second column in the following table gives the dates on which the depths to the water levels were measured.

The third column gives the depths from the points to the water levels, in feet and tenths of a foot. Thus in the well of C. H. Shaw the depth from the measuring point to the water level on October 29, 1929, is indicated to have been 57 feet. An asterisk (*) means that the measurement was not made by the representative of the United States Geological Survey or cooperating party but was reported by the owner, driller, or some other person.
