PREFACE

This report on the flood of January 1952 in the south San Fran-cisco Bay region and on the snowmelt flood of 1952 in the Kern Ri-ver, Tulare Lake, and San Joaquin River basins was prepared by he Geological Survey, Water Resources Division, C. G. Paulsen, chief, under the general direction of J. V. B. Wells, chief, Sur-ace Water Branch, and under the general supervision of R. C. Briggs, district engineer.

Basic records of discharge in the areas covered by this report are collected in cooperation with the Department of Public Works of California, through the State engineer; the Corps of Engineers, Department of the Army; the Bureau of Reclamation, Department of the Interior; the city of San Francisco; the Turlock and Modesto rrigation districts; Alameda County Flood Control and Water Con-servation District; and licencees of the Federal Power Commis-sion.

Several individuals and organizations contributed to this report. The Corps of Engineers furnished the information and statistics on lood damage. In part 1, a summary of the meteorological con-ditions associated with the flood-producing storm was furnished y Don L. Jorgensen, research forecaster, U. S. Weather Bureau; records of reservoir contents during the flood period and supple-mentary precipitation records were furnished by the Santa Clara Valley Water Conservation District, the San Francisco Water De-artment, and the San Jose Water Works. In part 2, the records or Kern River near Bakersfield were furnished by the Kern Coun-y Land Company.

TABLES

San Francisquito Creek, and the contiguous basins of Soquel Creek, San Lorenzo River, and Pescadero Creek that drain directly into the Pacific Ocean. The streams and their gaging stations and principal reservoirs are shown on plate 6. Table 1 lists these gaging stations and reservoirs and the numbers and letters that identify them on plate 6.

The three Pacific Ocean basins drained by Soquel Creek, San Lorenzo River, and Pescadero Creek, are classified as "mountain and foothill" areas, their slopes being greater than 200 feet per mile. Utilization of the waters of these streams is of relatively minor importance. By contrast, water for irrigation is a prime necessity in the highly developed Santa Clara Valley, which is the valley floor of all the streams draining into San Francisco Bay that are delineated on the map, except for those of Alameda and San Lorenzo Creek basins, and is highly developed agriculturally. The many reservoirs shown on the map (pl. 6) are primarily for conservation purposes, but the larger ones also have an important flood-control function. The gaging stations in the Santa Clara Valley are, in general, at the mouths of canyons from which the streams debouch onto the valley floor. A notable exception is the station on Guadalupe River at San Jose, which is out on valley floor proper. Of the two basins not a part of Santa Clara valley, Alameda Creek above the Niles gaging station drains an area that is about 85 percent mountain and foothill terrain, and virtually all of the San Lorenzo Creek drainage basin above the Hayward gaging station is in that category. There is little utilization of San Lorenzo Creek water, but Calaveras Reservoir in the Alameda Creek basin stores water for municipal use by the city of San Francisco.

Elevations in the south San Francisco Bay region range from slightly above sea level to more than 4,000 feet and topography has a marked influence on rainfall distribution and intensity. Average annual precipitation has a range of from about 14 inches in the valley to more than 60 inches in mountainous areas. There is often a marked relationship over large areas between storm precipitation and average annual precipitation. With rare exceptions, virtually all the precipitation occurs between mid-October and the latter part of April. Snow rarely falls in measurable quantities except at the highest altitudes. There is no record of floods that have been augmented to any appreciable extent by melting snow.

General Description of the Flood

The flood of January 11-13, 1952 caused considerable damage in the south San Francisco Bay region, particularly in the drainage basins of Alameda Creek and Guadalupe River. Flood conditions in the Guadalupe River basin were considerably alleviated,

Table 1.--Stream-gaging stations and principal reservoirs in south San Francisco Bay region

however, by the modifying effect of storage reservoirs on the tributary streams and on Coyote Creek. Virtually the entire flow of Coyote Creek was stored in Coyote and Anderson Reservoirs. The effect of this storage in reducing potential flood damage in northwestern Santa Clara County becomes evident when it is realized that the only divide between Coyote Creek and Guadalupe River in their roughly parallel courses through the city of San Jose to San Francisco Bay is formed by the leveelike banks of silt that had been deposited by the streams at high stages.

Rain began to fall on the morning of January 11; it increased in intensity during that afternoon and night but slackened by noon of January 12. Streams began to rise on the afternoon of January 11; they rapidly peaked during the morning hours of January 12 and spread over the lowlands. Many highways were closed by slides and floodwater. In the towns of Campbell, Milpitas, San Jose, and Santa Clara, hundreds of basements and lower floors were flooded. Alviso, at the mouth of Guadalupe River, was inundated to depths ranging from 6 inches to 10 feet, causing all but about 50 of the town's 700 population to leave. In the Pleasanton area of Alameda Creek basin, many people were forced to leave their water-logged homes and farms. Floodwaters were slow in receding because the rain, which stopped on the 13th, began again on January 14 and continued for the next few days.

Flood Damage

No loss of life was attributable to the flood, but damage amounted to about $1,400,000. Table 2 summarizes the damage by type and by drainage basin.

Meteorology and Precipitation

Meteorology

[Prepared by Don L. Jorgensen 1/]

The heavy rains in the San Francisco Bay region during the 11th and 12th of January 1952 resulted from a storm that moved southward out of the Gulf of Alaska. On the morning of the 11th this storm was centered about 300 miles west of Portland, Oreg., with the storm front extending southward just off the coast of northern California. By the evening of the 11th the front had moved inland over Oregon and extreme northern California, and had become nearly stationary in the vicinity of the San Francisco

1/ Research forecaster, U. S. Weather Bureau.

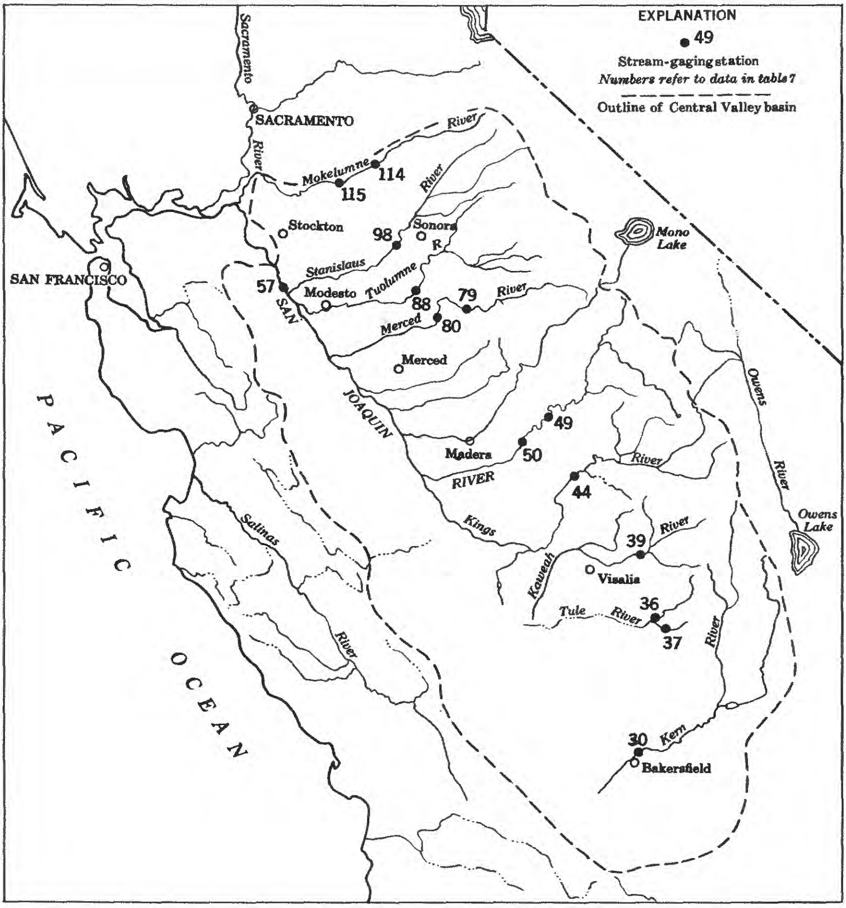

Figure 76. --Map showing location of gaging stations and outline of Central Valley basin.

The North and South Forks of the Kern River rise in the Sierra Nevada at an altitude of 14,000 feet near Mt. Whitney and drain the upper Kern River basin, about 2,400 square miles of the west slope of the Sierra, above the foothill line east of Bakersfield. These streams flow south to join at a point downstream from Kernville and within the reservoir formed by the partly completed (1952) Isabella Dam. From their juncture the main stem flows westward through a narrow canyon to emerge onto the valley floor within 18 miles of Bakersfield. Thence, the river flows southwesterly, over the valley floor for about 39 miles to Buena Vista Lake, a natural sump now modified by cross levees. The bed of the lake is cultivated when not inundated for streamflow storage purposes. Flow into the lake is artificially controlled. Floodwaters not stored in the lake for later irrigation use are diverted into Buena Vista Channel through which they may flow northwesterly through Sand

Ridge to Tulare Lake. Floodwaters may also reach Tulare Lake via Goose Lake Slough, a distributary channel of Kern River downstream from Bakersfield.

Tule River drains an area of about 390 square miles on the lower slope of the Sierra Nevada to the west of the upper Kern River basin. The main stream is formed by the confluence of the North and Middle Forks about 10 miles northeast of the point where it emerges from the foothills at Porterville. The South Fork joins the main stream 6 miles east of this point. Floodwaters flow westward across the valley through old delta channels to Tulare Lake.

Kaweah River drains a mountainous area of about 520 square miles east of the foothills north and west of and separated from the upper Kern River basin by a secondary ridge paralleling the main crest of the Sierra Nevada. Its headwaters rise in glacial lakes at an altitude of more than 12,000 feet. The main stream is formed about 10 miles upstream from the head of its delta by the confluence of the North, Middle, and South Forks near the town of of Three Rivers. Below the foothills it divides into several distributaries that cross the delta fan and enter Tulare Lake.

The headwaters of the Kings River rise in lakes and snowfields at altitudes of as much as 14,000 feet, and drain a mountain area of about 1,700 square miles, north of the upper Kaweah River basin. The South and Middle Forks unite at an altitude of about 2,200 feet, and the North Fork joins the main stream at an altitude of about 1,000 feet just upstream from the eastern end of Pine Flat Reservoir. Near the town of Piedra and about 4 miles downstream from the partly completed (1952) Pine Flat Dam, the river emerges from the foothills onto the valley floor, where it has built up a large delta. At a point about 25 miles south of the city of Fresno the river divides, part flowing northerly (as Kings River North) through James bypass and Fresno Slough to the San Joaquin River, and part flowing south (as Kings River South) to Tulare Lake. The Corps of Engineers has constructed control works and levees in the vicinity of the division point.

Little runoff reaches the bed of Tulare Lake except in years of exceptionally large flow. In order to facilitate farming the lake bed, a network of levees has been constructed to confine the water to as small an area as possible. Inflow amounting to 5,000 acre-feet can be stored between the leeves of the inlet channels. Inflow in excess of this amount will breach these levees and flood one or more of the cells within the network of levees in the lake bed. Part of the water stored is pumped out again for irrigation, and the remainder evaporates.

San Joaquin River rises in the Sierra Nevada northwest of the Kings River basin at altitudes above 10,000 feet, flows southwesterly until it emerges from the foothills onto the valley floor, thence westerly to a point midway on the valley floor near the town of Mendota, where it turns northwesterly to the delta and its confluence with Sacramento River at the head of Suisun Bay. At the edge of the foothills Millerton Lake, a reservoir formed by the construction of Friant Dam in 1941, affords storage capacity of 520,000 acre-feet. Above the reservoir the river drains a mountain area of about 1,600 square miles, and an aggregate of about 338,000 acre-feet of storage space is provided in five upstream reservoirs operated for power. Below Friant Dam the principal tributaries rise in the Sierra Nevada and enter the main stem from the east. From south to north they are: Fresno, Chowchilla, Merced, Tuolumne, Stanislaus, Calaveras, and Mokelumne Rivers. The principal reservoirs in the mountains and foothills provide usable storage capacity of about 281,000 acre-feet on Merced River, 646,000 on Tuolumne River, 162,000 on Stanislaus River, and 349,000 on Mokelumne River.

Description of the Flood

Antecedent Conditions

During the 1951-52 water year, precipitation in all the Central Valley basin was consistently greater than normal throughout the the winter. Widespread storms began in October and occurred intermittently until the end of March. The largest storms came in December and January. Most of the storms brought abnormally cold air and produced snow down to and below an altitude of 1,000 feet. Very little of this snow melted and a very large snow pack accumulated over the entire mountain area.

On April 1, 1952, the accumulated snow pack was 260 percent of normal in the Kern River basin, from 190 percent (Kings River) to 265 percent (Tule River) in the Tulare Lake basin, and from 180 percent (Merced and Tuolumne Rivers) to 200 percent (Stanislaus and Mokelumne Rivers) in the San Joaquin River basin. As shown in table 6, this snow pack, in all basins, exceeded that existing on the same date in 1938, which had been the greatest pack on record since the beginning of the California Cooperative Snow Surveys record in 1930. Moreover, examination of available records of snowfall at stations in these basins indicates that the 1952 snow pack equalled or exceeded the pack that caused the great snowmelt floods of 1906.

Thus, in April of 1952 enough snow had accumulated to cause the greatest snowmelt flood on record. That such a flood did not occur was largely due to the temperature pattern during the snowmelt period. Weather continued to be cold; temperatures from April through July were generally below normal-in June about 5° below normal. Moreover, the occasional intervals of hot weather that usually cause the peak flows during the period of the snowmelt runoff were short and not as hot as usual.

Table 6. --Comparison of snow packs existing on April 1 for the years 1938 and 1952 in the Kern River, Tulare Lake, and San Joaquin River basins expressed in percent of normal computed for the 62-year period 1880-1951, inclusive.

[Data from State Division of Water Resources, California Cooperative Snow Surveys]

Drainage basin	Average snow pack in basin (percent)	
	1952	1938
Kern River	260	205
Tulare Lake	195	155
Tule River	265	180
Kaweah River	220	155
Kings River	190	155
San Joaquin River:		
Upper San Joaquin River	190	170
Merced River	180	140
Tuolumne River	180	150
Stanislaus River	200	170
Mokelumne River	200	155

Flood Runoff

As it occurred, the volume of the April-July runoff approached closely that of 1938, and on Kern, Kaweah, Stanislaus, and Mokelumne Rivers exceeded it (see table 7). However, in no case where the period of the record includes the year 1906 did the 1952 snowmelt runoff exceed that of 1906. Figure 76 shows the location of the gaging stations listed in table 7.

As shown in table 7, the maximum daily discharge during the April-July runoff period was greater than the corresponding discharge in 1938 on the Kern, Kaweah, and Mokelumne Rivers. However, on those streams where the period of the record includes the year 1906, the maximum daily discharge during the snowmelt period did not exceed that of 1906.

the station near La Grange, the maximum daily outflow from Don Pedro Reservoir occurred on May 16 and was 11,300 cfs. The corresponding outflow during the 1938 snowmelt floods was 19,000 cfs. The record daily discharge near La Grange of 20,200 cfs was established during the snowmelt floods of 1906, before construction of the existing reservoirs.

On Stanislaus River, the maximum daily discharge below Melones Dam was 11,600 cfs as compared with a discharge of 13,700 cfs during the 1938 snowmelt period. The runoff volume for the period April through July, totaling 1,320,000 acre-feet, was slightly greater than that of 1938.

Although there was more than 180,000 acre-feet of combined storage space in Salt Springs and Pardee reservoirs on April 1, snowmelt flows of Mokelumne River exceeded downstream channel capacities. Salt Springs Reservoir filled about July 10 and Pardee Reservoir about July 4. Pardee Reservoir was operated for flood control purposes by the East Bay Municipal Utility District. As recorded at the Lancha Plana gaging station, the maximum daily outflow from Pardee Reservoir was 5,110 cfs on June 11. The corresponding discharge in 1938 was 4,850 cfs and occurred on May 16. In 1906, before the upstream reservoir development, the maximum daily discharge of snowmelt runoff at the station near Clements was 9,000 cfs. Total April-July volume of runoff at Lancha Plana in 1952 was 737,000 acre-feet and exceeded that of 1938 by 86,000 acre-feet. In 1906, the corresponding volume near Clements was 1,020,000 acre-feet.

An indication of the effectiveness of the principal reservoirs in the San Joaquin River basin in regulating the large April-July volumes of snowmelt runoff both in 1938 and in 1952 is shown by the data in table 8.

Extent and Character of Flooding

Damaging floods occurred along lower reaches of Kern River, principally along upper Goose Lake Slough and in Buena Vista Lake. Although floodwaters were stored in the lake and dams constructed across outlets of the river impounded water for future irrigation use in the Sand Ridge area, a total of 30,700 acres of agricultural lands--in native pasture or planted to cotton, alfalfa, and grain--was flooded; this total includes about 23,500 acres in Buena Vista Lake, 200 acres along Goose Lake Slough, and 7,000 acres that were intentionally flooded in the Sand Ridge area. Several county roads were washed out by flows in Goose Lake Slough, and one road was damaged near Tulare Lake.

Table 8. --Storage increment in principal reservoirs of the San Joaquin River basin during snowmelt period April 1-July 31, for the years 1938 and 1952.

Tributary basin	Reservoir	Storage increment April 1-July 31 (acre-feet)	
		1938	1952
Upper San Joaquin River--	Florence Lake------------	64,100	63,900
	Huntington Lake-----------	69,300	77,500
	Shaver Lake---------------	93,900	124,800
	Millerton Lake -----------	-------	159,900
Merced River -----------	Lake McClure ------------	49,700	14,500
Tuolumne River ---------	Lake Eleanor-------------	1,700	14,900
	Hetch Hetchy -------------	224,100	248,800
	Don Pedro ---------------	25,300	110,700
Stanislaus River---------	Melones -----------------	10,900	55,900
Mokelumne River--------	Salt Springs --------------	86,500	108,700
	Pardee ------------------	71,800	72,600

Upstream from the Tulare Lake area, about 300 acres of agricultural lands were flooded by Tule River water augmented by water from Kaweah River via Elk Bayou. Minor flooding occurred on Kings River as the result of a levee break upstream from Crescent weir, and on Kings River North about 5,100 acres were inundated within the levees. About 1,100 acres of crop lands along the Kings River downstream from the town of Laton suffered damage from seepage produced by the continuous high flows.

Major flooding occurred in the Tulare Lake area. Floodwaters from Kings, Kaweah, and Tule Rivers began entering Tulare Lake early in the snowmelt period, and water in the lake reached a maximum of about 500,000 acre-feet on or about June 20. As estimated by the Corps of Engineers, total volume of inflow to the lake during the snowmelt period amounted to 490,000 acre-feet. The corresponding inflow in 1938 was 850,000 acre-feet. A total of 72,700 acres of agricultural lands in Tulare Lake was flooded. Of this total, crops had been harvested on 14,700 acres before inundation. Levee failures within Tulare Lake occurred from March until June 2.

Below Friant Dam on the San Joaquin River about 2,500 acres of pasture and crop lands were flooded; in addition, 400 acres of crop lands were affected by water seeping through levees and canal banks along the river for about 15 miles upstream from Mendota Dam. Maximum releases from Millerton Lake in combination with a maximum inflow of about 4,600 cfs of Kings River water via

Fresno Slough produced a peak of about 8,800 cfs near Mendota on May 29. Downstream from Mendota Dam, inflow from the principal tributaries produced flows in excess of channel capacity at nearly all points along the lower San Joaquin River. Near Vernalis, and downstream from the confluence of Stanislaus River, the maximum daily discharge of 33,700 cfs on June 1 was only 3,900 cfs less than the corresponding discharge in 1938 on June 7. Between Mendota and the San Joaquin River delta, 77,600 acres of agricultural lands were flooded in scattered areas inadequately protected by levees and in normal overflow areas. About 65,700 acres of the flooded area was native pastureland and the remainder was cropland. An additional 10,600 acres of cropland was damaged by seepage through and under the levees, owing to the long duration of the period of high flows. Major levee breaks occurred near Dos Palos, in the reach between the Tuolumne and Stanislaus Rivers, and in Reclamation District 2075 downstream from the Stanislaus River. A large recreational area between the levees near Mossdale, many residential properties, and several miles of paved county roads were flooded.

About 2,600 acres of crop and pastureland and a county road were flooded, when overbank flow inundated bottom land along both banks of the Merced River in a narrow strip extending from the vicinity of Livingston to the mouth of the river.

Aside from the flooding of about 500 acres of river bottom land near its mouth and seepage damage to 190 acres of cropland below Tuolumne City bridge, flows from the Tuolumne River added substantially to the flooding along the San Joaquin River.

On the Stanslaus River, the flooded area extended from the vicinity of Oakdale to the San Joaquin River. It included about 4,100 acres of river bottom lands, of which 1,300 acres were in cultivated crops and the remainder in pasture. Near the mouth of the river about 1,200 acres were severely affected by seepage of water through the levee.

Agricultural lands flooded along Mokelumne River included about 3,900 acres near the confluence of the Cosumnes and Mokelumne Rivers; 650 acres, inundated by a levee break, near Lockeford; and 640 acres in a narrow belt along the river between the towns of Lockeford and Lodi. Waste-disposal works of several wineries along the river were damaged by floodwaters.

Flood Damage

During and immediately following the 1952 snowmelt floods, the Corps of Engineers began a survey of flood damage. This survey, which required approximately three months to complete, included the collecting of all available reports of damage by other agencies, and the making of personal interviews with many property owners and the personnel of local organizations, public utilities, and private firms that had suffered damage. The data on flood damage were embodied in a report presented by the Sacramento District, Corps of Engineers, entitled, "Report of 1952 Snow-Melt Floods, Sacramento-San Joaquin River Basins, California and Great Basin, California, Nevada, and Utah."

Table 9 as taken from that report gives the flooded areas and the flood damage in the Kern River, Tulare Lake, and San Joaquin River basins under four categories of damage. In these three basins, damage incurred as a result of the 1952 snowmelt floods included the flooding of 200,900 acres and amounted to a total of $11,828,000 distributed as follows:

Type of damage	Amount	Percent of total
Agricultural	$10,113,000	85.5
Residential	8,000	.1
Commercial and industrial.	25,000	.2
Public institutions, and public and private utilities.	1,682,000	14.2
Total:	$11,828,000	100.0

Table 9.--Flooded areas and flood damages, Kern River, Tulare Lake, and San Joaquin River basins, snowmelt flood of 1952.

[Compiled by Corps of Engineers]

Basin and stream	Flooded area (acres)	Direct flood damage			
		Agricultural	Commercial and industrial	Public institutions and utilities	Total
KERN RIVER BASIN					
Kern River	a 30,700	$1,210,000	0	$5,000	$1,215,000
TULARE LAKE BASIN					
Tule River	300	40,000	0	17,000	57,000
Kings River	5,200	136,000	0	63,000	199,000
Tulare Lake	72,700	6,877,000	0	1,418,000	8,295,000
Total, Tulare Lake basin	78,200	b 7,053,000	0	1,498,000	8,551,000
SAN JOAQUIN RIVER BASIN					
San Joaquin River:					
Friant to Mendota	2,500	60,000	0	10,000	70,000
Mendota to Merced River	60,900	728,000	$6,000	31,000	765,000
Merced R. to Tuolumne River	8,100	139,000	0	2,000	141,000
Tuolumne R. to Stanislaus River	3,300	150,000	0	13,000	163,000
Stanislaus River to Delta	5,300	414,000	14,000	26,000	c 462,000
Merced River	2,600	71,000	0	3,000	74,000
Tuolumne River	(d)	14,000	0	0	14,000
Stanislaus River	4,100	204,000	0	84,000	288,000
Mokelumne River	5,200	70,000	5,000	10,000	85,000
Total, San Joaquin River basin	92,000	e 1,850,000	25,000	179,000	c 2,062,000
Total, Kern River, Tulare Lake, and San Joaquin River basins	200,900	$10,113,000	$25,000	$1,682,000	$11,828,000

[a] Includes 23,500 acres in Buena Vista Lake.
[b] Includes $127,000 seepage damage.
[c] Includes $8,000 residential damage.
[d] Nominal.
[e] Includes $810,000 seepage damage.
