# Techniques for Estimating Streamflow Characteristics in the Eastern and Interior Coal Provinces of the United States

By Kim L. Wetzel and J.M. Bettendorff

## Abstract

Techniques are presented for estimating various streamflow characteristics, such as peak flows, mean monthly and annual flows, flow durations, and flow volumes, at ungaged sites on unregulated streams in the Eastern Coal region. Streamflow data and basin characteristics for 629 gaging stations were used to develop multiple-linear-regression equations. Separate equations were developed for the Eastern and Interior Coal Provinces.

Drainage area is an independent variable common to all equations. Other variables needed, depending on the streamflow characteristic, are mean annual precipitation, mean basin elevation, main channel length, basin storage, main channel slope, and forest cover.

A ratio of the observed 50- to 90-percent flow durations was used in the development of relations to estimate low-flow frequencies in the Eastern Coal Province. Relations to estimate low flows in the Interior Coal Province are not presented because the standard errors were greater than 0.7500 log units and were considered to be of poor reliability.

## INTRODUCTION

The environmental concerns associated with coal mining led to the enactment of the Surface Mining Control and Reclamation Act of 1977. In recognizing the adverse effects that coal mining may have on water resources, this law requires that (1) each mining-permit applicant make an analysis of the potential effects of the proposed mine on the hydrology of the mine site and adjacent area, (2) "an appropriate Federal or State agency" provide to each applicant hydrologic information on the general area prior to mining, and (3) measures be taken by mining permittees to control any adverse effects of mining on the hydrologic balance and on reclamation of the land. The available data on streamflow characteristics do not satisfy current demands by the coal-mining industry for information.

## Purpose and Scope

The purpose of this report is to provide techniques for estimating streamflow characteristics that can be used by surface-mine owners and operators in preparing permits as well as by regulatory agencies in determining the adequacy of permit applications.

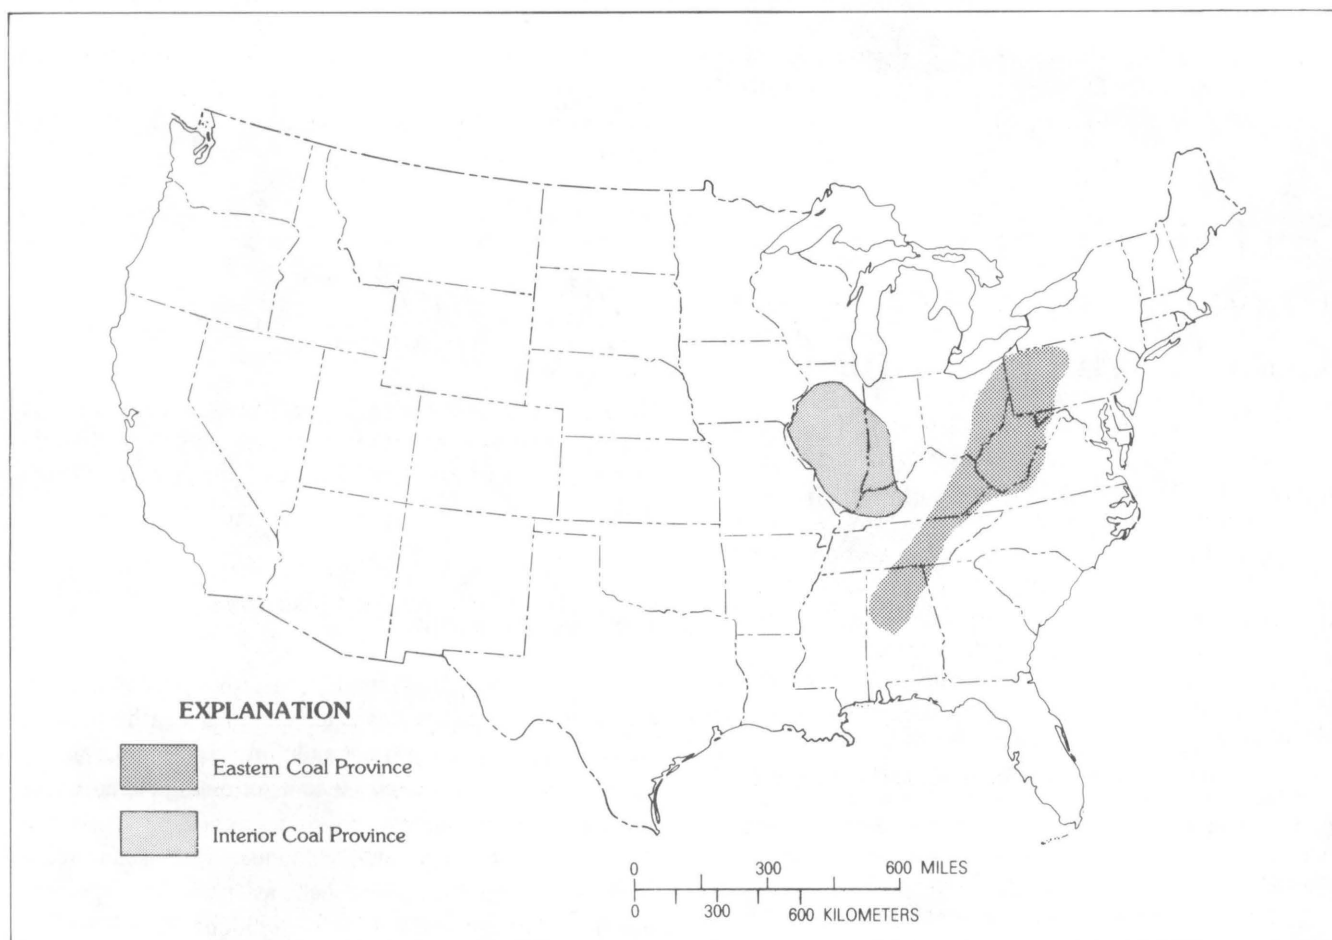

Multiple-linear-regression techniques were used to relate streamflow characteristics such as peak flows, mean monthly and annual flows, flow durations, flow volumes, and low-flow frequencies measured at 629 gaging stations to available drainage-basin characteristics. Regression equations were developed for the Eastern and Interior Coal Provinces of the United States.

## Location of Study Area

The Eastern Coal region is divided into several smaller coal provinces, two of which are the Interior and Eastern Coal Provinces (Trumbull, 1960). Figure 1 shows the location of both provinces which together cover parts of 11 States in the Eastern United States.

## DATA

The regression analyses in this report are based on streamflow data collected prior to October 1979 at 629 continuous-record gaging stations in the Eastern Coal region. Of these stations, 140 are in the Interior Coal Province (86 in Illinois, 31 in Indiana, and 23 in western Kentucky). The remaining 489 stations represent the Eastern Coal Province; these are distributed as follows: 87 in Pennsylvania, 74 in Ohio, 101 in West Virginia, 22 in Maryland, 60 in Virginia, 56 in eastern Kentucky, 43 in Tennessee, and

**Figure 1.** Locations of the Eastern and Interior Coal provinces.

46 in Alabama. Gaging stations having at least 10 consecutive years of unregulated record were selected for the analyses. Locations of the gaging stations are listed in tables 1A and 1B (all tables are at end of report) and are shown, together with coal-province boundaries, in plate 1.

All data used in this evaluation were obtained from the WATSTORE Streamflow/Basin Characteristics file, which is maintained by the U.S. Geological Survey.

## Basin Characteristics

Drainage-basin characteristics used in the regression equations can be determined from the U.S. Geological Survey's 7.5-minute topographic maps and from plate 2 of this report. The characteristics of each station are given in tables 1A and 1B and are described as follows:

1. Drainage area (AREA), in square miles, is the area that contributes directly to surface runoff. This area can be planimeted from topographic maps.
2. Main channel slope (SLOPE), in feet per mile, is the difference in elevation at points 10 and 85 percent of

the distance along the channel from a reference site, such as a gaging station, to the basin rim, divided by the channel distance between the two points.

3. Main channel length (LENGTH), in miles, is the length of the channel from the gaging station to the basin divide, which can be determined from topographic maps.
4. Forest cover (FOREST), as shown by a green tint on Geological Survey maps, is expressed as a percentage of the drainage area. It can be determined by the method of counting intersections on a superimposed grid.
5. Mean annual precipitation (PRECIP), in inches, is determined for the centroid of the drainage basin from corresponding isohyets shown on plate 2 (U.S. Department of Commerce, 1974).
6. Mean basin elevation (ELEV), in feet above National Geodetic Vertical Datum of 1929, is determined by averaging the elevations at the intersections of a grid that has been superimposed on a topographic map. The grid spacing is selected so that at least 25 intersections fall within the basin boundary.

- 7 Storage (STORAGE), expressed as a percentage of the drainage area, includes lakes, ponds, and wetlands shown on topographic maps

## Flow Characteristics

Streamflow characteristics used in the regression analyses are listed in tables 2A through 2I and are described as follows

- 1 Peak flows corresponding to the 2-, 5-, 10-, 25-, 50-, and 100-year recurrence-interval flood discharge
  - 2 Mean monthly and annual flows
  - 3 Flows that have 10-, 25-, 50-, 70-, 75-, 90-, and 95-percent probabilities of exceedance as daily means
  - 4 Flow volumes corresponding to 2-, 10-, 25-, 50-, and 100-year recurrence intervals for 3-, 7-, 15-, and 30-day high-flow averages of daily means
  - 5 Low flows corresponding to 2-, 5-, 10-, and 20-year recurrence intervals for 3- and 7-day low-flow averages of daily means
- All flows are expressed in cubic feet per second

## TECHNIQUES FOR ESTIMATING STREAMFLOW CHARACTERISTICS

A relatively small sample of streams are gaged. Consequently, data are not available for many sites for which information is needed. The procedure adopted for this study involved the development of regional regression equations to relate flow characteristics to easily measured basin characteristics. The relations provide a means of estimating streamflow characteristics at ungaged sites. These relations may also provide improved estimates for gaged sites for which periods of record are short or disrupted.

### Regression Models

In this study, the multiple-linear-regression technique is used to formulate a relationship between observed values for streamflow characteristics and values of easily measured basin characteristics for a sample of gaged sites.

The general form of a multiple-linear regression is

$$Y = a + b_1 X_1 + b_2 X_2 + \dots + b_n X_n, \quad (1)$$

where Y is a streamflow characteristic (dependent variable, for example, mean monthly streamflow for October),  $X_1$  to  $X_n$  are basin characteristics (independent variables), a is a regression constant, and  $b_1$  to  $b_n$  are regression coefficients.

Nonlinear relationships between hydrologic variables have frequently been found to be linear if the variables are transformed to logarithms. The general form of a log-transform relation is

$$\log Y = \log a + b_1 \log X_1 + b_2 \log X_2 + \dots + b_n \log X_n \quad (2)$$

An equivalent form of equation 2 is

$$Y = a X_1^{b_1} X_2^{b_2} \dots X_n^{b_n} \quad (3)$$

Because the logarithm of zero is undefined, a constant of 1.0 is added to the two independent variables that could feasibly be zero, forest cover (FOREST) and basin storage (STORAGE).

### Selection of Independent Variables

As a preliminary step in regionalization, the transformed station values were grouped on the basis of the two coal provinces. Several "trial and error" regressions had to be computed for each streamflow characteristic to derive the best equations. To improve the linear fit of the equations, a constant of 30.0 was subtracted from the precipitation (PRECIP) values before they were transformed.

The final selection of a set of independent variables to form each regression equation was based on the following considerations:

- 1 Each independent variable must be significant at the 95-percent confidence level.
- 2 The combination of independent variables should have the lowest standard error of estimate compared with other combinations.
- 3 Combinations of cross-correlating independent variables should be kept to a minimum.

The regression equations were not accepted solely on the basis of statistical tests. The independent variables and regression coefficients of each equation were judged from the standpoint of knowledge of the streamflow processes. The sign of the regression coefficient indicates a direct (positive) or inverse (negative) effect on the dependent variable. If the sign of the regression coefficient was contrary to the basic understanding of the process involved, that independent variable was not used in the final regression equation.

### Regional Regression Analysis

The residuals (differences between the streamflow characteristic values and the corresponding values computed from the regression equations) were used to determine the fit of each station within its respective group (i.e., province). In general, the residuals within each group were randomly

distributed. The magnitudes and areal patterns of the residuals were used to attempt to regionalize or regroup the stations. The regression results did not show any improvement over the original equations.

The residuals for the two groups were correlated with drainage area to identify any possible subgroups based on drainage-area size. Again, there was no appreciable decrease in the standard errors for any of the possible subgroups.

The regression relations for both provinces are listed in tables 3A through 3H. In general, these tables show several relations for each flow characteristic. The first line of values for each dependent variable shows the most accurate relation using only one independent variable, and succeeding lines indicate a more complex equation of increasing accuracy. The last line of values for each streamflow characteristic shows the most accurate relation containing only variables significant at the 95-percent confidence level.

Two additional variables were developed in an attempt to explain the variability of low flows. These variables were ratios of the 50- to 90-percent observed flow durations and the 25- to 75-percent observed flow durations. Regression analyses were performed using these additional variables to improve the standard errors. In the Interior Coal Province, these variables were not significant at the 95-percent confidence level. The most accurate equations had standard errors greater than 0.7500 log units and have not been included in the report.

In the Eastern Coal Province, the 50- to 90-percent duration ratio (RATIO) was significant at the 95-percent confidence level. Table 3I lists these relations for the low flows. The first three lines for each dependent variable show equations of increasing accuracy as the number of independent variables increase. The standard errors for the most accurate relations using three variables ranged from 0.1899 to 0.2967 log units. The fourth line shows the most accurate relation before the development of the flow-duration ratios. These standard errors ranged from 0.4761 to 0.6908 log units.

Observed flow-duration values may not always be available. Relations were also developed using a 50- to 90-percent duration ratio (CALCRATIO) calculated from the most accurate relations in table 3E. The last line for each low-flow characteristic in table 3I shows these relations. The standard errors ranged from 0.4767 to 0.6934 log units and did not show significant improvement over the best relation available not using duration ratios.

## Limitations of Estimating Equations

The standard error of estimate, in percent, is a measure of how well the sample data fit the relation expressed by the regression equation. Two-thirds of the observations

for a flow characteristic lie between the plus and minus percent errors.

The correlation coefficient ( $r^2$ ) computed for each relation measures how much of the variation in the values of the dependent variable is accounted for by the independent variables. Values of  $r^2$  can range from 0 to  $\pm 1$ . A value of  $r^2$  equal to  $\pm 1$  indicates a perfectly linear relationship. In general, the larger the value of  $r^2$ , the better the model. The standard errors of estimate, in log units and plus and minus percent, and the correlation coefficients are listed in tables 3A through 3I.

The relationship between a streamflow parameter and basin characteristics given by a multiple-linear-regression equation is assumed to be linear only within the range of characteristics that defined the relation. Ranges in the values of the basin characteristics used to develop the regression equations are given in table 4. The suitability of the equations for values outside these regions and ranges is unknown.

Histograms showing the distribution of gage sites by drainage-area size for both coal provinces are shown in figures 2A and 2B. Percentages of gaging stations that had drainage areas between 20 and 1,000 square miles were 71 in the Interior Coal Province and 76 percent in the Eastern Coal Province.

## Examples

The following examples show the procedure used to estimate an unknown streamflow characteristic. Estimates are made for gaged sites, allowing a comparison of the computed results with the observed values given in the tables.

**Example 1** Estimate the mean monthly flow for April (Q4) of Camp Creek near Camp Creek, W. V. (station 03178500).

- 1 The site is located in the Eastern Coal Province, as shown in plate 1.
- 2 Table 3C shows that the basin characteristics used in the Q4 relationship are drainage area, precipitation, and mean basin elevation.
- 3 Topographic maps can be used to determine the drainage area as 32.0 square miles and the mean basin elevation as 2,710 feet above sea level. AREA=32.0, ELEV=2,710.
- 4 From plate 2, the mean annual precipitation in the drainage basin is estimated as 40.0 inches. PRECIP=40.0-30.0=10.0.
- 5 Determine the mean monthly streamflow for April through the use of the regression equation.  

$$Q4 = 0.318 \text{ AREA}^{0.984} \text{ PRECIP}^{0.450} \text{ ELEV}^{0.123}$$

$$Q4 = 0.318 (32.0)^{0.984} (10.0)^{0.450} (2,710)^{0.123}$$

$$Q4 = 0.318 (30.3) (2.82) (2.64)$$

$$Q4 = 71.7 \text{ cubic feet per second}$$

**Figure 2A.** Histograms showing numerical distribution of gage sites by drainage-area size intervals, for the Eastern Coal Province

The mean monthly flow for April given in table 2C is 74.5 cubic feet per second.

**Example 2.** Estimate the 7-day, 10-year high-flow volume (V<sub>7,10</sub>) for Kickapoo Creek at Peoria, Ill. (station 05563500).

1. The site is located in the Interior Coal Province, as shown in plate 1.
2. Table 3H shows that the basin characteristics used in the V<sub>7,10</sub> relationship are drainage area, precipitation, and forest cover.
3. Topographic maps can be used to determine the drainage area as 297 square miles and the forest cover as 19.3 percent.  
AREA=297, FOREST=19.3+1.0=20.3.
4. From plate 2, the mean annual precipitation in the drainage basin is estimated as 34.5 inches.  
PRECIP=34.5-30.0=4.5.

**Figure 2B.** Histograms showing numerical distribution of gage sites by drainage-area size intervals, for the Interior Coal Province

5. Determine the 7-day, 10-year high-flow volume through the use of the regression equation.

$$V_{7,10} = 5.17 \text{ AREA}^{0.934} \text{ PRECIP}^{0.514} \text{ FOREST}^{0.068}$$

$$V_{7,10} = 5.17 (297)^{0.934} (4.5)^{0.514} (20.3)^{0.068}$$

$$V_{7,10} = 5.17 (204) (2.17) (1.23)$$

$$V_{7,10} = 2,820 \text{ cubic feet per second}$$

The actual high-flow volume given in table 2H is 2,670 cubic feet per second.

**Example 3.** Estimate the mean annual flow (QA) for Corey Creek near Mainesburg, Pa. (station 01516500). All three regression equations will be used to show how the equation improves as independent variables are added.

1. The site is located in the Eastern Coal Province.
2. Table 3C shows that the basin characteristics needed are drainage area, precipitation, and elevation.
3. Using topographic maps, the drainage area is determined as 12.2 square miles and the elevation as 1,670 feet above sea level.  
AREA=12.2, ELEV=1,670.

- 4 Plate 2 is used to estimate the mean annual precipitation in the basin as 34.5 inches  
 $PRECIP = 34.5 - 30.0 = 4.5$
- 5 The regression equation, constants, coefficients, and solutions are  
 $QA = a \text{ AREA}^{b_1} \text{ PRECIP}^{b_2} \text{ ELEV}^{b_3}$

a	b <sub>1</sub>	b <sub>2</sub>	b <sub>3</sub>	QA
1.40	1.00			17.1
378	993	0.513		9.8
082	991	534	0.204	9.9

The observed mean annual flow is 12.7 cubic feet per second (table 2C)

## SUMMARY

The equations in this report, based on data for 629 stream-gaging stations in the Eastern and Interior Coal Provinces, provide a means of estimating selected streamflow characteristics of unregulated streams. These equations are not intended to replace sound hydrologic judgment or any computational procedures that can be successfully applied to sites where sufficient data are available to permit calculation of reliable estimates. Rather, they are intended as tools for estimating streamflow characteristics for sites where little or no data are available.

Regression methods were used to relate the streamflow statistics—peak flow, mean monthly and annual flow, high-flow volumes, flow durations and low flow—to basin

and climatic characteristics. Drainage area is the only independent variable common to all regression equations. Additional variables used in the equations are mean channel slope, forest cover, mean annual precipitation, main channel length, mean basin elevation, and storage.

\* Number in ( ) is power of 10 by which value must be multiplied

**Table 4.** Ranges of basin characteristics in the Eastern and Interior Coal Provinces

Basin Charac- teristics	Maximum	Eastern Coal Province			Maximum	Interior Coal province		
		Minimum	Mean	Median		Minimum	Mean	Median
Area <sup>1</sup>	6,850.0	0.67	442.0	177.	4,690.0	2.10	500.0	211.
Slope <sup>2</sup>	380.0	.66	27.3	13.2	53.9	1.0	7.0	4.6
Length <sup>3</sup>	315.0	1.20	46.2	32.0	253.0	2.2	53.2	36.2
Forest <sup>4</sup>	100.0	.0	59.5	66.0	78.0	.0	15.3	10.3
Precip <sup>5</sup>	58.0	34.0	44.7	44.0	50.0	33.4	39.6	38.5
Elev <sup>6</sup>	3,690.0	210.0	1,560.0	1,400.	948.0	400.0	676.0	696.0
Storage <sup>7</sup>	6.0	.0	.62	.12	4.41	.0	.38	.12

<sup>1</sup> Area, in square miles

<sup>2</sup> Main channel slope, in feet per mile

<sup>3</sup> Main channel length, in miles

<sup>4</sup> Forest cover, in percent of drainage area

<sup>5</sup> Mean annual precipitation, in inches

<sup>6</sup> Elevation, in feet above sea level

<sup>7</sup> Storage, in percent of drainage area
